But national particularism is not alone in becoming intermingled with this new philosophy. A still more remarkable osmosis tends to combine pure speculation with political exuberance. M. Wahl sagely observes that American philosophy is essentially a philosophy of democracy. According to James, the American nation was founded upon what may be called the American religion – was instituted and developed in the faith that a man needs no master to direct him, and that the common people are quite able, by their own united efforts, to work out their salvation. He attempts to conceive a vision of a world in harmony with democratic ideals, and with the 'great adventure' which democracy stands for in the universe. Anglo-Saxon 'pluralism' is in one sense the metaphysical expression of the ambition for an 'all-pervading democracy'. That is the reason why it pictures the world as an immense swarm, with no established order or hierarchy, the wills of all members being equal in importance – as William James himself might say, quite like a great republican banquet.

But, after all, what is pluralism? A vague term for a vague idea, emotional rather than intellectual in content, pluralism can be understood chiefly by its opposite. It is a reaction from Hegelian monism, which absorbs all diversities into the unity of the 'absolute' – a theory which Bradley popularized in Anglo-Saxon countries. All philosophy that refuses to be 'monistic' is 'pluralistic'.

Pluralism is found in England and America in all sorts of phases. In itself it is distinct from pragmatism, a point upon which James and Schiller are equally insistent. But in actual fact it has been *developed* pragmatically, especially by the author of *Pragmatism* and of *A Pluralistic Universe*.

James is of special interest to us because of this, and because he is himself a perfect example of a '*nature pure*', in the sense that Goethe gave to that term. The perfectly definite combination of puritanism, romanticism, and empiricism that he personifies makes him an eminently representative type. He does his philosophizing openly, I might almost say cynically, through his sentiments and his preferences, even through his temperament – a philosophy being, in his opinion, essentially an expression of temperament. In this he illustrates clearly one of the most fundamental aspects of the pragmatic method. This method demands that the philosopher, in relying upon subjectivity of emotion itself to attain his object, should enter into as material a contact with affairs as is possible; should devote his whole being to knowledge and sensation; should explore the actual with his own powers of desire and emotion, so that he may be able to judge all things in conformity with himself, according to the state of his own activity and his own sensations in contact with them. He abandons himself to emotional gymnastics, as it were; he enlarges, stretches, and expands his psycho-physiological *ego,* to the end that he may play upon it as upon an instrument of knowledge; all in vain, we insist frankly, because this entire effort depends far too much upon the infinite scope of the intelligence, and can never achieve anything beyond a marionette performance entirely out of keeping with philosophy.

William James also teaches a sort of pure nominalism, which, after the manner of Hume and Stuart Mill, but even more decidedly than either of them, he proceeds to apply concretely. He has a native hatred of the abstract, which he is not content to display in theory alone, but which actually passes over into his practical philosophy. He "cramps himself within the concrete."

The world of the pluralist, a chaos of conflicting wills, of contrasts, and of contradictions, is made in the image of his own temperament, of his own romantic imagination, of his own fevered will, of his mystical materialism. Harshness, violence, tempest, floods, heights, depths, risk, peril, combat, danger, terror, sweat, struggle – "human nature straining in all its powers ... on the rack, human nature *in extremis*" – this is the way he sees the world. "Pioneers, O Pioneers!" sings Walt Whitman, "Fresh and strong the world we seize, world of labor and the march, Pioneers! O Pioneers!" A sensuous tumult, indeed, a meaningless commotion. A very tiresome uproar. These great heroes of 'energy', who give such tremendous buffets to the universe, do not know what constitutes the most genuine and powerful activity. Saint Paul in his prison, Saint John on his Isle of Patmos, Saint Gertrude in her cell, – even Descartes in his little library, – and Rembrandt in his studio, – were active in a more intense and dramatic way than all the pioneers of Walt Whitman in the "world of labor and the march."

"A friend," wrote William James, "told me one day that the thought of my universe made him sick." For James, and also for Schiller, reality is not comprehensible except through a multiplicity of heterogeneous truths, and of

incommensurable principles, sometimes contradictory, one quite as legitimate as the other, because reality is only a system of semblances on which our activity is supported; there is a multiplicity of 'realities' and of universes – the universe of every day, the universe of science, one of poetry, one of mythology, and so forth, and so forth; so many distinct and independent universes, more or less intermingled with one another, overlapping or confused according to our method of approach to things and our practical attitude toward the world. It is a concept that does not exactly make us sick, as it did the friend of the philosopher, but it does, we confess, seem to us remarkable for its puerility, and not free from a certain very sophomoric presumption.

If this is the cosmology of integral 'moralism', what is its theology? Here the study of pluralism becomes especially captivating; indeed we may say that the reality surpasses all our hopes. With a charming intrepidity, the pluralist philosophers, especially James (for Schiller is much more modern), offer us an unalloyed type of practical and anti-intellectual theology.

One of the main reasons for the success of pluralism in England and America is the fact that it reinstates the religious instinct and offers support to the naïve and trusting religion of simple souls, which was menaced by the withering atheism of Hegelian monism. It is amusing to note that Hegelism in the first place invaded England in the name of religion and of the higher truths or Christianity, which it was supposed to defend against skepticism and against utilitarian materialism.

However this may be, the Anglo-Saxon pluralists approach all questions concerning God and the ultimate verities with their usual attitude of radical empiricism and unalleviated pragmatic 'moralism'.

God exists, because the notion of a God lends more grandeur to our vision of the world, more majesty to metaphysics, and at the same time makes the world less bleak, and more homelike for us; because, in order to meet life courageously, we need a powerful ally with whom we can exchange personal services.

God is not omnipotent. The omnipotence of God would be incompatible with the absolute individuality of men and women. Does not our liberty imply that we are independent of Him? Do we not defy Him when we do evil? Would there, indeed, be any evil in the world if God had power to prevent it? Henry James was told by his son that God was not sufficient unto himself, that he needed our partnership, that he acted like 'an honest workman', busy with us at a common task.

Such is the God of the pragmatist: a celestial comrade, a powerful factor in the course of events, an ally and also a servitor – a servitor who is likewise exacting, who throws us into danger and into all sorts of unexpected emergencies, in order to develop our highest possibilities.

We have seen how the American pluralists are deliberately reverting to the most primitive religious beliefs and concepts. Yes, but a civilized degenerate is something a good deal lower than a savage. This religion pretends to protect

certain practical attitudes, a certain moral residue of Christianity, in the absence of all the powerful principles and vital certainties of the Christian faith.

"Polytheism is the natural complement of pluralistic philosophy," writes M. Jean Wahl. Possibly he takes the republican philosophy of Renouvier and the truculent hypotheses of William James a little too seriously. But the fact remains that polytheism is really in actual fact directly in the line of development of Anglo-Saxon pluralism – that it is, as it were, its natural culmination; and it is the more remarkable that pluralism does not represent simply the notion of any one philosopher, but that it is a great philosophical movement, a national philosophy.

Can this return to polytheism, as the final result of an exclusively moralistic method of approach to religion and of a radical renunciation of rational speculation in that field, throw any light upon the psychological origin of primitive polytheism? At least, the question is singularly suggestive. There is a sort of wicked pleasure in watching the wise ones of this world tending toward such outrageously degraded concepts, after they have for three centuries harshly accused the Catholic faith of being anthropomorphic, idolatrous, subversive of human reason, hostile to the laws of nature, superstitious in its worship of the saints, a revival of paganism, and the rest. And now, here they are arriving at polytheism – rehabilitating fetishism in the wake of Auguste Comte, and announcing themselves as supporters of an avowed anthropomorphism in the style of Renouvier. Thus we find that James and his pluralistic friends – with their 'crass supernaturalism', with their finite, democratic, and national God, a God who is at once protective, serviceable, redoubtable, and ready to take part in a mysterious exchange which is profitable and advantageous to both parties – are reviving a sort of negroid form of religion.

They mean well, to be sure; they are influenced by the most large-hearted motives; the original longings and aspirations from which their philosophy had its rise are healthy and sound in themselves. But good intentions are not enough in philosophy any more than they are in politics. And there is an essential dishonesty in pretending to solve the most difficult and momentous problems without an earnest search for the truth (*sans vouloir la vérité*), first virtually submitting to the amputation of their own intellectual organ, and then resorting to a method of reasoning chosen simply because of its obvious and radical unsuitability to the subject under consideration. The agnostics, who, first admitting the powerlessness of human reason in such matters, simply refuse to make any statements about divine subjects, are essentially more honest thinkers than these philosophers overflowing with religious zeal, who change the glory of the incorruptible God into an image made like to corruptible man.

PREFACE

Henri Bergson. "Préface." *William James: Extraits de sa correspondance*, ed. Floris Delattre and Maurice Le Breton (Paris: Payot, 1924), pp. 7–12.

Au cours d'une des dernieres conversations que j'eus avec William James, nous vînmes à parler des congrès de philosophie. Un de leurs principaux avantages, lui disais-je, est de nous montrer l'homme que nous connaissions seulement par ses livres, et de nous faire ainsi mieux comprendre ce qu'il a écrit. « Eh oui, me répondit-il; et parfois, quand on a vu l'homme, on n'a plus du tout envie de lire ce qu'il a écrit. » C'est possible; mais de William James je certifie qu'on ne pouvait pas, quand on l'avait vu, ne pas vouloir lire tout ce qu'il avait écrit. Modeste, discret, volontiers silencieux, il avait beau faire: un foyer ardent était là, dont on recevait chaleur et lumière. Jamais je ne me suis trouvé avec lui sans penser à la définition que son compatriote Emerson avait donnée de la personnalité vraie: « une réserve de force, qui agit par sa seule présence. »

On se croira un peu en sa présence quand on lira les lettres dont MM. Floris Delattre et Maurice Le Breton publient aujourd'hui une traduction singulièrement vivante en même temps que scrupuleusement fidèle. Tout de suite apparaîtra ce don de vision directe qui frappait d'abord chez William James, – vision des choses, vision des âmes. Il avait failli être peintre; on a conservé de lui des croquis où se révèle une aptitude remarquable à saisir le trait caractéristique, à noter des attitudes, à fixer des gestes. Mais combien plus perçant encore était son regard quand il le dirigeait sur la vie intériéure! Certes, ses *Principes de Psychologie* sont d'un grand savant: fondateur du premier laboratoire de psychologie expérimentale qu'on ait eu en Amérique, spécialement préparé par ses études médicales à utiliser les ressources de la psychologie pathologique, il a su tirer parti des méthodes les plus neuves. Et pourtant la véritable nouveauté du livre, son originalité profonde réside dans l'application que l'auteur a faite du procédé le plus ancien, le plus connu, le plus banal: l'observation intérieure. Cette méthode semblait avoir fourni tout ce qu'elle pouvait donner; et voici qu'entre les mains de James elle faisait l'effet d'un instrument dont on se fût servi pour la première fois. Ce que nous avions pris jusqu'alors pour une description de faits apparaissait comme un tissu d'idées préconçues, d'hypothèses, de théories; le voile tombait, qui s'interpose chez chacun de nous entre sa conscience et sa personne; on apercevait l'âme humaine à nu. Cette fraîcheur de vision, que nous admirons

dans les livres de William James et qui a fait de lui un psychologue incomparable, nous la retrouvons dans sa correspondance. Elle s'associait chez lui – on en sera particulièrement frappé en lisant ces pages – à une incapacité native d'accepter ce qu'il peut y avoir d'artificiel et de conventionnel dans notre manière habituelle de parler et de penser. Cette disposition d'espirit était communicative: on s'en fût voulu de rien dire à James qui n'eût été directement aperçu, personnellement éprouvé. Seules comptaient d'ailleurs, quand on avait affaire à lui, les choses de l'âme; toute autre préoccupation s'effaçait. J'ai gardé le souvenir de notre première rencontre, depuis longtemps combinée par un échange de lettres à travers l'océan, plusieurs fois contrariée par les circonstances. Je crois bien que nous nous dîmes bonjour, mais ce fut tout: il y eut quelques instants de silence, et tout de suite il me demanda comment j'envisageais le problème religieux.

Ce n'est pas par simple curiosité qu'il s'iritéressait ainsi à la pensée ou, comme il disait, à la « vision » d'autrui. Quand la vision était dégagée de toute idée préconçue, elle lui fournissait des matériaux – les seuls auxquels il tînt réellement – pour l'élaboration de sa philosophic. Il ne voulait rien sacrifier de l'expérience; et comme il croyait à des courants de réalité multiples, plus ou moins indépendants les uns des autres, se juxtaposant et s'entrecroisant pour faire un « univers pluralistique », il allait les chercher dans les consciences individuelles qui en subissaient l'influence et qui les manifestaient. Ainsi fut composé son ouvrage sur *Les variétés de l'expérience religieuse*. Quand parut ce livre admirable, beaucoup n'y virent qu'une série de descriptions et d'analyses, – une psychologie, disaient-ils, du sentiment religieux. Combien ils se trompaient sur l'intention de l'auteur! La vérité est que James voulait prendre ici sur le vif, comme dans une observation scientifique, la force par laquelle l'âme religieuse est transportée ou soulevée. Au-delà de cette âme, mais à travers elle et déjà dans l'ébranlement qu'elle reçoit, il allait chercher l'objet auquel elle s'attache. Toute impression directe lui était ainsi matière a philosopher. Par là s'explique la sympathie avec laquelle il se penchait, pour les regarder, sur les thèses qu'on opposait aux siennes, quand elles lui semblaient réellement traduire une impression. Nous parlions un jour des philosophes qui ne croient pas à l'action libre, au libre choix. « Ceux qui pensent ainsi, me dit-il, sont tout bonnement des hommes qui n'ont jamais eu le sentiment vif d'agir, soit que leur vie toute spéculative ne leur en ait pas fourni l'occasion, soit plutôt que leur nature les incline à se laisser porter par les circonstances. Ne leur reprochons pas de ne pas entrer dans nos vues. Ils nous livrent les résultats de leur expérience, et ils nous rendent service en le faisant. »

La philosophie a presque toujours été une grande simplification du réel. Avec Platon, elle remonta des choses individuelles à des genres, et de généralité en généralité prétendit s'élever à une idée capable de tout embrasser. Plus tard, considérant la diversité des faits plutôt que celle des choses, elle voulut, de loi

en loi, atteindre un principe d'explication universel. Mais, dans un cas comme dans l'autre, elle ne voyait dans la réalité que l'expression multiple et changeante de la vérité, laquelle serait une, simple, systématique. Elle se détournait de ce qui donne aux faits leur variété, aux choses leur individualité, au monde ses aspects pittoresques et changeants. A l'artiste de s'en préoccuper, disait-on, et non pas au philosophe; ou bien alors c'est à la négation même de la philosophie, sous le nom d'empirisme, qu'on aboutira. La grande originalité de Wil1iam James est d'avoir retenu cette diversité, de s'être attaché à cette variété, et d'avoir pourtant abouti à une philosophie. C'est qu'il se représente la connaissance philosophique et scientifique, la vérité en général, sous une forme nouvelle. Son « pragmatisme », sur le sens duquel on s'est à tel point mépris,[1] définit précisément la conception de la vérité qui est impliquée dans sa manière de philosopher.

Il ne peut être question de l'exposer, pas plus que de résumer la doctrine. Ceux qui connaissent la philosophie de James la comprendront mieux après avoir lu sa correspondance. Les autres trouveront ici, avec une extraordinaire abondance de réflexions instructives et suggestives, intéressantes pour ceux-là même qui s'intéressent le moins aux généralites philosophiques, la meilleure introduction a l'oeuvre du maître. Tous verront comment la doctrine s'est constituée, du premier au dernier jour de la vie intellectuelle de James, par le développement organique d'un germe où elle préexistait. Le même élan qui porta William James de l'anatomie et de la physiologie à la psychologie, de la psychologie à la philosophie, le souleva de plus en plus haut vers une conception ou mieux vers une vision du monde qui embrassait tout le donné, qui tenait compte du désordre et de l'ordre, qui faisait une large place au hasard et à la chance, et qui, sans optimisme ni pessimisme, prenant la réalité avec le bien et le mal qui s'y trouvent, la jugeait indéfiniment perfectible par un effort insoucieux du risque. Doctrine séduisante et fortifiante, que le philosophe, comme on va voir, a vécue avant de la formuler.

On se plaît à en reconnaître l'originalité. Peut-être n'en a-t-on pas encore mesuré toute la profondeur, toute la portée. La postérité mettra William James à sa vraie place. Elle dira sans doute que ce penseur fut un des plus grands, et que nul ne fit un plus vigoureux effort pour étreindre la réalité.

WILLIAM JAMES AND THE MAKING OF PRAGMATISM

F. C. S. Schiller. "William James and the Making of Pragmatism." *The Personalist* 8.2 (April 1927): 81–93.

Presented at the Sixth International Congress of Philosophy held at Harvard University Sept. 13–19, 1926, and printed by its permission.

At the recent Congress of Philosophy at Harvard I was considerably surprised to hear what very modest and apologetic estimates were put on American achievements in philosophy by some of the spokesmen of America in welcoming the representatives of foreign countries. I could not but think this modesty a sacrifice of truth to politeness, when I reflected first on the paucity of the really important discoveries which form the bright spots in the history of philosophy and, secondly, on the very great importance of one achievement which indisputably stands to the credit of America. I mean, of course, the development of Pragmatism, and as I was myself involved in it, and can testify to some aspects of it which are not generally known, and am moreover unfortunately growing old, I wish to avail myself of this opportunity in order to give reasons, before it is too late, for my conviction that the origination of Pragmatism was one of the major events in the history of thought, and to put on record certain incidents connected with the origination of Pragmatism which came within my personal knowledge.

But before I do so, let me first justify my remark about the rarity of really important novelties in the history of thought. They cannot indeed be enumerated on the fingers of one hand, but one does not need to be four-armed, like an Indian God, in order to accommodate all the conceptions which can be accounted first-class discoveries.

I find I cannot recognize more than *nine* of such discoveries. Of these I should credit the first, the *Absolute* or *One* of Monism, to the Hindus, although a case may perhaps be made out for Parmenides for an equal share in this discovery. Still it was in India that the ethical and logical implications of this monistic line of thought were worked out in their completest and most consistent form. The next two, *Pure Spirit* and *Universals* must both be set down to Plato. Aristotle, another Greek, is the undisputed father of *Formal Logic*. In Western thought, at any rate, Descartes, a Frenchman, is the first

philosopher to discover the *Self*; though it had long been familiar to language and long been exploited in the East, and with true philosophic modesty even been identified with the Absolute. The honor of discovering the *Critical problem*, and the claim that the epistemological question takes precedence over the ontological, must I think be divided between England and Germany, between Locke and Kant, though neither of them succeeded in constructing a consistently critical philosophy, though not even their followers could swallow either system as it stood, and though, in some aspects, both seem to have been anticipated by the Sophists and Sceptics of antiquity. On the other hand a definite recognition of the *Problem of Value* seems to be first traceable in Germany. Its origin is obscure, but it is clearly post-Kantian and post-Hegelian; and as its significance is still largely unexplored, it may be said to be still at the beginning of its philosophic career.

Of *Darwinism* the effective birth-place is England, as that of *Pragmatism* is America: but in both these cases it was found, after the new doctrine had won its way to recognition, that anticipations of it, often of a very definite kind, could be traced all the way back to the Greeks. So far, the earliest Darwinian on record is Anaximander, and the earliest pragmatist, Protagoras: but they were both so far ahead of their times that their words fell upon deaf ears. This is due to a persistent feature in human psychology. The first hundred times or so that a new idea is ventilated, it is simply disregarded, and treated as though it had never been; the one hundred and first time. when some forceful genius gets the world by the long ears and makes it listen, the learned can always show that it was anticipated long ago. So they are satisfactorily confirmed in their conviction that there is nothing new under the sun! Nevertheless Pragmatism was as new as anything could be in the fog-laden atmosphere of philosophy.

Under these circumstances the best proof of an idea's novelty is to be found in the completeness and grotesqueness of the way in which it is misunderstood; and certainly, judged by this test, the novelty of Pragmatism ranks amazingly high. Its putative parent, Peirce, was so shocked by the fame of the doctrine fathered upon him, and so dismayed by the Herculean exploits which it accomplished even in its cradle, that he was actually driven to disown his paternity, and to take refuge in a "pragmaticism" which, he said, was ugly enough to be left severely alone. He has thereby provided philosophy with a superb example of the folly of a *gran rifiuto*, though he has not yet found a Dante to damn him for it. Its real progenitor, James, could hardly restrain his nearest and dearest pupils from participating in the congenial labor of misrepresenting what they had never understood.

The whole of Continental Europe, with a perhaps pardonable ignorance of English idiom, cried out that the demand that truth must "work" and "pay" was just a piece of the banausic sordidness and vile commercialism of the American mind, endeavoring to degrade the highest and most sacred spiritual

values to mere matters of dollars and cents. Even the champions of the Hegelian Absolute found it an intolerable strain upon its (theoretically infinite) elasticity to swallow the new doctrine and to absorb, transcend, transmute and transmogrify it in its all-engulfing maw. I myself can well remember what an uproar was aroused at the Heidelberg Congress of Philosophy in 1908 by my innocent remark that Pragmatism was a philosophic movement which had originated in America. The Germans took it as an intolerable piece of impertinence for a philosophic movement to originate in America, and it was no use pleading that this happened to be sheer historical fact.

Amid this hubbub no one noticed that the very doctrines which all were furiously denouncing had long been before them, and indeed had excited general and unstinted admiration under another name. So long as William James enunciated his views under the label of "psychology," what he said was accepted and applauded; but when he called the same views "philosophy," he was decried as a subverter of the pillars of the Temple of Truth. For a detailed proof of the correctness of this comment I may refer to an excellent little book which deserves to be better known in America, *The Philosophy of William James*, by H. V. Knox.[1] It is largely a string of quotations, and expounds James's Pragmatism almost wholly in his own words; and the best of the joke is that he has selected his most significant quotations from the *Principles of Psychology!*

Now that was in 1914, and by that time some of us had "caught on." I myself cannot claim to have been much less obtuse than the general mass of philosophers. John Dewey alone had had the perspicacity to detect the philosophy that was contained in James's psychology and to derive his "instrumentalism" independently from that fountain head. I myself had been delighted with James's *Will to Believe*, and had expressed myself pretty freely in a review which appeared in *Mind* for October, 1897. This may have done something to attract the attention of English philosophers to William James, who was at that time practically unknown, at least in Oxford. Still I could not then claim any status as a disciple of James. I had only met him about twice; though five minutes after meeting him the first time I found myself talking to him as if I had known him all my life. It ought to be impressed on all American students of philosophy, from their Freshman year on, what a very great man James was. I have only met two men I should call really great, and Arthur Balfour is the other. Still, when the California Lecture on *Philosophical Conceptions and Practical Results* baptized Pragmatism and flung it into the stream of philosophic controversy, I could in no wise set up as an authority on the meaning and the mind of James. I knew that he was a man after my own heart, but there were others far better qualified than I to pronounce upon his views.

[1] London, Archibald Constable, 1914.

Dickinson Miller was one of these, a friend and a favorite pupil of James. He was also a friend of mine, and at that time I knew him better than I knew James. In January, 1899, he wrote a subtle and impressive article in the *International Journal of Ethics*, called *The Will to Believe and the Duty to Doubt*, criticizing the doctrine of the will to believe, and not long afterwards sent it to me with a request that as an admirer of James's I should write a reply to it. He had, it seems, asked James to reply, but the latter had refused.

I read the article and wrote to Miller that I was aware that he knew James much better than I did but that I could not but think that he had seriously mistaken James's meaning, giving my reasons. Miller sent my letter to James, and asked him to decide between us. To my great delight, James decided in *my* favor. Then for the first time did I realize the enormous capacity of the philosophic mind for misconstruing James. It would otherwise never have entered my own mind that the particular misconception Miller had fallen into was even possible. The point at issue between us was one which still plays a part in the attacks on Pragmatism, and for which there has never seemed to me to be the slightest justification. It concerned the question whether a pragmatist was entitled by his theory to believe whatever he liked, or in other words whether Pragmatism failed to distinguish between a truth and a truth-claim. I pointed out to Miller that he had failed to allow for the empirical side of James's doctrine of the verification or refutation of a belief by experience of its working.[2]

This still seems to be one of the major difficulties its critics have with Pragmatism. For apriorism is not so much a doctrine, or even a faith, as a habit or aberration of mind. Whether or not there are *a priori* truths there are certainly *a priori* prejudices. And these are so impenetrable that they cannot even conceive the idea that experience of its working may be regarded as relevant to the truth of an idea. And so they are quite impervious to the neatness and beauty of the suggestion that the secular dispute between apriorism and empiricism might be terminated by an equitable compromise, which found a use for *both* of them, admitting that there were *a priori* truth claims galore, and in fact that nearly every one was chock full of them, but not that they were on this account self-proving and self-evident truths, and able to dispense with testing by their working in experience.

As I reflected on the situation, this voluntaristic compromise, which alone seems to assign a meaning and a function both to our anticipations of experience and to their corroboration and confirmation by experience, and which moreover could bestow logical respectability on the all-pervasive activities of our will to believe, seemed to be exactly what was required. Accordingly when I had occasion to write a contribution to the volume of

[2] Miller does actually quote one of the many passages in James which insist on this, but shows that he has not perceived its significance.

Essays subsequently known as *Personal Idealism*, I chose this as my subject, and entitled it *Axioms as Postulates*.

I conceived my task as that of tracing throughout the established structures of the intellectual world the manifold operations of that volitional activity whose existence and potency James had revealed, under the name of the will to believe, in a single case. And I was hopeful that by so universalizing it I could render its recognition easier and more palatable. For I had been taught as a youth that this was precisely the way in which Kant had overcome and confuted the scepticism of Hume. Hume had shown, unanswerably, that causality was not an objective fact of observation but a subjective infusion into the series of events. He had inferred that it was an illegitimate addition which vitiated our knowledge. But Kant had turned the edge of Hume's contention by accepting its premises and drawing a different conclusion. Subjective additions to our data were not limited to the case of causality. They were to be found in every corner of the field of knowledge. Indeed it was impossible to cultivate this field, without the use of the elaborate machinery, which Kant proceeded to describe with so much detail and obscurity that thousands of philosophy professors have lived on the *Critique of Pure Reason* ever since. This Kantian machinery of Categories, and so forth, was in a sense subjective: but it generated the only sort of objectivity which it was possible to recognize or needful to know. So the lethal weapon with which Hume had hoped to strike a deathblow at knowledge, not only became innocuous in Kant's hands, but actually essential to the only objectivity that existed or had meaning.

So why should one not, thought I, repeat this Kantian feat and turn the will to believe, which intellectualistic system-builders had so long rejected, into the keystone of our edifice? It seemed conceivable that even Kantians might welcome such an enterprise. For, after all, Kant had not left his system so logically complete, so perfectly symmetrical and harmonious, as he had tried to make it. Even the most faithful Kantians could not but perceive that the system was traversed by a glaring inconguity. There was no logical connection between Kant's treatment of the Pure and of the Practical Reason. The latter, though psychologically rooted in Kant's idiosyncrasy, had very much the air of an afterthought, attached to the former by a transparent artifice. But, if it were taken seriously as a logical principle, it clearly embodied a thought which transcended intellectualism altogether, and could be made to yield quite a novel account of the mental activity which gave form and meaning to the data derived from experience The process of postulation, which Kant had admitted in only a niggardly and reluctant way for the special purpose of getting himself out of a difficulty, could be construed more widely and generously. It could be given logical status, and shown to enter into the operation of all our cognitive functions. It could be universalized like the will to believe, and identified with it, or traced to a common root with it in our volitional nature.

It would then be capable of generating the whole of the mind's *a priori* furniture and of accounting functionally for the whole structural *a priori*. The result would be a completely and consistently *voluntaristic* theory of knowledge such as had never yet been formulated.

So I set to work to show how all our *axioms* might be conceived as *postulates* which had suggested themselves as desirable if true, and had succeeded and survived, for transparent reasons, and could all be traced to the various activities of our will to believe. This is the genesis and history of my essay on *Axioms as Postulates*.

Of course I ought to have expected that the results would be disappointing. They always are. But they ought not to have been so disappointing, if the Kantians had been more seriously concerned with the truth of Kant and the coherence of his system. They seemed to be content with tracing its history and tabulating the dates on which its various sections might be presumed to have been written, in short with leading the easy, merely parasitic, life of the industrious commentator. For the analogy which seemed so clear to me, between Kant's relation to Hume and my relation to Kant and to James, they had no eyes at all. And the historians of philosophy, those most stalwart devotees of the copy-theory of truth, continue to represent the epistemological alternatives as two, the rationalist and the empirical, both equally intellectualistic, and equally inadequate. The possibility of a synthesis, which would transcend this antithesis by taking both "reason" and "experience" in a voluntaristic way, continues to be ignored. No doubt it is felt that to recognize it would be too disturbing to traditional classifications, and would upset too many familiar "categories." But is it not one of the saddest tragedies of philosophy that it should be so much easier for a rich man's automobile to pass the portals of the Heavenly Jerusalem than for anything new to get into the histories of philosophy and for anything old that has once got into them to drop out?

But to continue my reminiscences: after having been rebuffed in my well-meant attempt to mediate in the epistemological wrangle between "rationalism" and "empiricism," I turned my attention to the excogitation of a suitable *name* for our new manner of philosophizing. For it had very soon been borne in upon me that "pragmatism" was a thoroughly bad name, and almost sufficient to damn any dog that bore it. Not only did it not explain itself, but it did not even, at a first hearing, suggest any hint of the direction in which its meaning was to be sought. All that it could suggest was indeed definitely misleading. Etymologically, it was derived from *Pragmata*, but its etymology told one nothing about what it thought about "things." To those ignorant of Greek, it conveyed a connection with "practice" which was a dangerous half-truth; to those familiar with obsolescent English it was associated with "knavery"; to Germans it seemed to tamper wantonly with the well-established meaning of an existing term. Worst of all, it took about

half an hour to explain its meaning properly, and how rarely did one have that half-hour granted one!

So considering all these things, I determined to adopt the term "humanism," which seemed significant and apt, and was not encumbered with old senses likely to interfere and to be confused with its philosophic use. It had moreover already been employed in senses very cognate to that which I wanted; sporadically indeed, but by good authorities. Thus Pringle-Pattison had used it in his *Man's Place in The Cosmo?*[3] and Dickinson Miller had actually applied it to James's philosophic attitude in the very article that had provoked my intervention.[4]

Accordingly I proposed to James that he should change the name to Humanism. But he refused, on the ground that the name Pragmatism had already been taken up and had established itself. Of course it had been taken up with joy by the adversaries of the new way of thinking; for they had realized with terror how dangerously popular its appeal might easily become, and perceived with delight what a handicap an obscure technical name like "pragmatism" would be. Their really crushing criticism which they never uttered in public but used to whisper confidentially into the ears of the elect, was that Pragmatism was "vulgar ;" how fortunate then that these heretical vulgarians had been foolish enough to choose to fight under so deterrent a banner!

It was a misfortune also that John Dewey and his vigorous Chicago School had no more attractive name to offer. They did yeoman service to the cause, and *almost* forced the academic world to treat it with the respect which is always accorded to systematic technicality. For the academic pedant always thinks in his heart, and occasionally all but says, "What I can understand, I despise." Now he frequently found Dewey hard to understand, and respected him accordingly; whereas James was such easy reading that the typical professional never attended properly to what he said, and invariably misunderstood him. Also Dewey's instrumentalism never inspired fear; even apart from its cumbrous name, it never threatened to become unduly popular. Though not so bad as "pragmatism," "instrumentalism" was a bad name too. It was too long, and ill equipped with cognate adjectives and verbs, and on the whole it is not surprising that it did not supplant "pragmatism" in philosophic use.

James, I think, realized, when it was too late, what a bad name "pragmatism" was. At any rate, so I was assured by Mrs. James in a precious letter which she wrote me, not long before her death, in response to my *Quarterly Review* article about her husband's *Letters*. This is how Mrs. James put it. On August 16, 1921, she wrote:

[3] P. 61.

[4] P. 176.

> I have read three times over your beautiful review of the Letters, and cannot tell you how it touches me. You are so much nearer to William than anyone else, and you speak for him as he could not for himself.... You are right in what you say of confessing to obligations which he never owed. It used to puzzle me in so strictly truthful a nature. Even Charles Peirce said to me "I never thought, much less taught, the views William says I did. I have very different opinions." For years poor C. S. P. had appealed to William for help until at last he acquired the habit of tugging that poor derelict through troubled waters. In one of the last quinquennial catalogues, Peirce changed his middle name from Saunders to Santiago. It was long before I understood that it was a way of calling himself St. James, but there it stands *Charles Santiago Peirce*. When William was a student in the chemical laboratory, and absorbed in philosophy, he found Charles Peirce a stimulating acquaintance; so when years after William sought to give a name to the faith he had long held, he glanced backward and said to himself, "I must have owed Pragmatism to Peirce." I protested and begged him not to handicap a cherished belief with so wanton a name. He was sorry afterwards, and preferred Humanism.

I shall never forget a confidential little lunch in my rooms at Oxford, to which I invited my friend, H. V. Knox, to meet James in order that we might both ask him what precisely he had owed to Bergson. He told us. When he had done, we both cried out, spontaneously and simultaneously, "But these are the very things which *we* have learnt from *you!*" He then admitted that it was possible that through the *Données Immédiates de la Conscience* had come out a year before the *Principles of Psychology*. Bergson might have read his earlier articles in *Mind* and have assimilated their ideas, and then have developed them in an original way which James thereupon found surprising and stimulating. I am afraid, therefore, that even though he did recognize that the name "pragmatism" was a mistake, his chivalrous willingness to give his enemies any verbal advantage they chose to claim, would always have kept him loyal to his mistaken choice!

Personally I found it quite easy to adapt myself to the situation. I could accept "pragmatism" as a generic term, of which "instrumentalism" and "humanism" could be species, as could an indefinite number of other views, more or less completely pragmatic, such as those of Poincaré, Mach and Ostwald, or more extreme, like those of Nietzsche and Vaihinger. For it was evident that, theoretically at least, there might be as many pragmatisms as there were pragmatists, and that Professor A. O. Lovejoy had grossly understated their numbers in limiting them to thirteen! For it was an essential feature of "pragmatism" to be recalcitrant to the scientific fiction which depersonalizes truth. If every "truth" originates with an individual thinker facing an actual problem and choosing the best solution that presents itself

to his mind, and framing the best judgment for containing it that he can conceive, and succeeding in winning the assent of others to the goodness of his judgment, it surely follows that its depersonalization is a fiction. It is obviously convenient and works pragmatically over a large field of investigation and no one would dream of denying its uses: still its legitimacy may be challenged at any point in any inquiry, should occasion to do so arise by our *agreeing* to approve each other's judgments and to sink our differences.

Nor can I see why this result should be decried as sceptical. It need not form a bar to understanding, any more than the fact that in using a common language we all have our personal, social and national peculiarities of voice, inflexion and pronunciation. It does not preclude agreement, but rather favors it. For it substitutes agreement for coercion, value for necessity, as the hall-mark of truth. And it brings out a social side to all truth-seeking, which should be a comfort to the "lone beast dwelling in his individual burrow," which James declared the philosopher to be, with so much painful truth.

This humanist truth, moreover, is not only social, but also democratic. By admitting that every center of experience should be heard from, because it may yield a contribution to the common store, it grants universal suffrage in the realm of thought, though it does *not* imply equality of value. For our individual guesses at reality and truth are inexorably judged by the value of their results. Every one has an inalienable right to his own opinion, to his personal reaction upon his world – until he can get a better. For the right to his opinion is the correlative of his duty to improve it. James was well aware of this, and was a true democrat who loved to appeal to the people, even in the most highly oligarchic preserves and the remotest recesses of philosophy. He summed up his position in the words of his immortal carpenter: "There is very little difference between one man and another: but what little there is is very important."

Moreover, in his democratic spirit he entirely agrees with his far-off ancestor, Protagoras, who also proclaimed the universal right of every man to find his own truth, and was martyred for making man the measure of all things by the Athenian oligarchs, twelve years before the vindictive democrats in their turn forced Socrates, the anti-democratic philosopher of authority, to quaff the hemlock-bowl! It is perhaps fortunate for some of us that the connection between philosophy and politics is no longer so direct! Philosophy has become less dangerous since those times; but it is now in danger of being merely dull. If, however, American philosophy, if philosophy anywhere, will only follow the lead of William James, it will not only escape this danger, but may again resume its ancient hegemony over the human strivings to attain to fuller and nobler forms of human life!

THE PLACE OF WILLIAM JAMES IN THE HISTORY OF EMPIRICISM

Ralph B. Perry. "The Place of William James in the History of Empiricism." *Proceedings of the Seventh International Congress of Philosophy*, ed. Gilbert Ryle (Oxford: Oxford University Press, 1931), pp. 480–486.

William James conceived it to be his role in philosophy to save empiricism through greater fidelity to its own tradition and standards.

The teachings which commended the British school to James and constituted its praiseworthy empiricism were two: the experimentalist doctrine that the events of sense-perception offer the only proof of existence; and the allied experiential doctrine that the essence of what exists, and the meaning of anything whose existence is debatable, are composed of the content of sense-perception. These are germinal doctrines, conceived by Locke, but reaching their full growth only in Hume and Mill. Thus Locke, while he affirms the peculiar 'adequacy' of the simple ideas of sense directly produced in us by existing things, nevertheless recognizes "in intuitive knowledge of our own,"[1] and a "demonstrative" knowledge of God's existence.[2] In Hume and Mill, on the other hand, the experimentalist test is so rigorously applied that even the existence of the external world has become highly questionable. As to the experiential doctrine of essence and meaning, James singled out for special approval Locke's transfer of the question of personal identity from the debatable ground of 'substance' to the evident ground of conscious selfhood. But the same Locke who thus reduced personal identity to terms of specific and plainly identifiable experiences was more indulgent towards the ideas of spiritual substance, bodily substance, power, and cause. He was candid enough to be troubled by them, but not radical enough either to reject them or to identify them with those data which were taken as evidence of them. Berkeley renewed the empiricist attack by reducing material substance to sense-perception. Hume and Mill completed the conquest by submitting spiritual substance, power, and cause to the same drastic treatment. James was not, as we shall see, satisfied with the account which these writers gave, but he credited them with having undertaken the task on empiricist principles.

[1] *Essay concerning Human Understanding*, 1853, p. 268.

[2] Op. cit., Book IV, Chapter iii, paragraph 21.

They looked for the phenomenal disclosure of these alleged entities, with the intention of reducing their meaning to that disclosure.

Viewed under one aspect, then, the course of British thought from Locke to Mill was conceived by James as a progressive revelation of the principles of empiricism and an extension of their application. Viewed from other angles, however, it was a transition from bad to worse – a progressive obscuring of empiricist principles, and contraction of their application. Thus there is a change from the liberal metaphysical and religious scope of the philosophies of Locke and Berkeley to the positivism of Hume and Mill, and to the scientific naturalism with which this positivism came to be associated. James's complaint of latter-day empiricism on this score pervades the volume of essays entitled *The Will to Believe*, and is explicitly formulated in the preface to that volume. He there speaks of "the half-way empiricism that is current under the name of positivism or agnosticism or scientific naturalism," meaning that it fails to apply to the scientific view of the world the fundamental empiricist maxim of regarding the "most assured conclusions concerning matters of fact as hypotheses liable to modification in the course of future experience."[3]

James's further complaint against the classic British empiricism was originally formulated in the essay *On Some Omissions of Introspective Psychology*, published in 1884, in which the author referred to the sensationalists and associationists who "end with the philosophical melancholy of a Hume at the conclusion of his treatise, or with Mill's dismal confession of failure at the close of his chapter on the Psychological Theory of Mind."[4]

He afterwards summarized this complaint as follows:

"Now, ordinary empiricism, in spite of the fact that conjunctive and disjunctive relations present themselves as being fully co-ordinate parts of experience, has always shown a tendency to do away with the connections of things, and to insist most on the disjunctions. Berkeley's nominalism, Hume's statement that whatever things we distinguish are as 'loose and separate' as if they had 'no manner of connection', James Mill's denial that similars have anything 'really' in common, the resolution of the causal tie into habitual sequence, John Mill's account of both physical things and selves as composed of discontinuous possibilities, and the general pulverization of all Experience by association and the mind-dust theory, are examples of what I mean."[5]

[3] *The Will to Believe*, 1898, Preface, pp. vii, viii.

[4] *Mind*, 9 (1884), pp. 8–9. Cf. also pp. 3–4, 26.

[5] *Essays in Radical Empiricism*, pp. 42–3. In this later period, James also recognized and repudiated the tendency to solipsism, evident in Berkeley and Mill, and attributed it to the same failure to make note of experiential conjunctions. Cf. *ibid*., pp. 76 ff.

In other words, empiricism, which ought of all philosophies to possess an alert sensibility, failed to find that which was under its very nose, and through this failure ended in shipwreck or suffered the even more mortifying fate of being rescued by its traditional rivals. Such being the failure of the major school of empiricism, James found only two men who seemed to him to have understood its causes and to have pointed the way to their removal. These two great reformers of empiricism and "foremost contemporary philosophers" of his time, were Charles Renouvier and Shadworth Hodgson.[6]

In 1872, writing to the author for the first time, he indicated the hope that Renouvier's philosophy, "par son côté phénoméniste," might attract English thinkers of the reigning empirical school, and divert this school from its current tendency to determinism and materialism. James's Renouvier was first of all "the greatest living insister on the principle that unity in an account of things shall not overwhelm clearness";[7] the philosopher who identified the real with the apparent, and knowledge with evident presence; who substituted 'representations' for substances or other hidden entities; who construed representations as embracing in their inherent duality of aspect both the subjective and the objective, and as standing in perceivable relations to one another, "multiple, composite, linked, interlaced."[8] Even Renouvier's doctrine of freedom itself is primarily an empiricist doctrine. It turns upon the nature of volition, and here James adopted Renouvier's view (the view of an "out and out phenomenist") that volition consists in "the stable survival" and motor discharge of representations.[9] Freedom is further supported by Renouvier's finitism and pluralism, this metaphysics being a direct outgrowth of his empiricist or phenomenist theory of knowledge. But it is supported, above all, by an empiricist interpretation of belief. The empiricist, renouncing all theoretical certainty save that felt in the immediate presence of particular facts, will recognize the inevitable discrepancy between the narrow range of theoretical certainty and the broad assurance of belief; and will conclude that the only sort of justification which such an excess of assurance over evidence can possess is a moral justification.

Shadworth Hodgson, like Renouvier, looked to the will, or practical reason, to offset the metaphysical limitations of empiricism. But to James,

[6] "The Sentiment of Rationality," 1879, *Collected Essays and Reviews*, p. 133. Cf. also pp. 26 ff.

[7] James, "The Sentiment of Rationality," *Mind*, 4 (1879), p. 325. Cf. "Bain and Renouvier," *Collected Essays*, p. 29.

[9] *Ibid*., p. 31; and *Pluralistic Universe*, p. 391 (note).

Hodgson was essentially the philosopher who keeps insisting that realities are only what they are "known as."[10] Like Renouvier, he wages war on behalf of phenomena against all substances and substrata. "The least and lowest meaning of the term Being," without which it would be meaningless, he says, "is perceivability."[11] While James cited him as an exponent of the general experiential principle, the influence of Hodgson is most evident in matters of detail,[12] illustrating the power of that principle to transcend the sensationalistic atomism of Hume.[13] Thus Hodgson proposes to consider the distinction between subjective and objective as a distinction appearing on a certain level of reflection, *within* the field of consciousness, and involving no reference beyond that field.[14] Similarly, the difference between concepts and percepts consists in the fact that every portion of the phenomenal field has both an 'actual character', and an 'expectant character' – "expectant as it waits for the completion of its relationship to other portions."[15] Again, consciousness is originally through and through temporal, and the substitution of a static juxtaposition of parts is an effect of analysis.[16] The minimum of consciousness is a 'process- content', a change or transition, which looks forward and back, having "as it were, one foot in the present, one elsewhere."[17] That which is at first in prospect shifts smoothly and uninterruptedly into retrospect. Thus the stream of experience is both continuous and interpenetrating. This is James's Hodgson, the apostle of the new empiricism.[18] There was

[10] *Pragmatism*, p. 50.

[11] *Metaphysics of Experience*, 1898, vol. i, pp. 262, 455. Cf. *The Method of Philosophy*, 1882, p. 19. In his *Philosophy and Experience*, 1885, Hodgson uses the term 'experientialism' to designate the radical appeal to experience or consciousness as distinguished from the positivistic or naturalistic empiricism. In fact, Hodgson uses the term 'empiricism' habitually for what is defective rather than for what is essentially sound in the philosophical school to which he attaches himself. Thus what is to James a word to conjure with is to Hodgson a term of disparagement.

[12] It was in 1910, reminiscently, and in writing to Hodgson himself, that James coupled that philosopher with Peirce as one of the two sources of his pragmatism; cf. *Letters*, ii, p. 328. In a letter to Renouvier, 8 May 1882, James wrote, "I find that all the good he does me is from details."

[13] Cf. Hodgson's *Time and Space*, p. 33. James's copy of this book is inscribed with the date 'December, 1875'. Cf. also *Philosophy of Reflection*, 1878, vol. i, p. 11.

[14] Cf. *Metaphysics of Experience*, vol. i, Book I, Chapters v–vii.

[15] *Philosophy of Reflection*, 1878, vol. i, p. 294.

[16] *Ibid*., p. 252.

[17] *Metaphysics of Experience*, vol. i, pp. 35, 42; cf. *Philosophy of Reflection*, vol. i, pp. 252–3.

another and to James a recreant Hodgson, who denied freedom, who reduced mind to dependence on body, who made inferences from consciousness to realities beyond, and was even tainted with monism. From this 'rationalistic' Hodgson, as from the a *priori* and speculative Renouvier, James was separated by a gulf that widened with the years and converted his relation into one of personal affection and reminiscent gratitude.

Let me now, in conclusion, briefly summarize James's own philosophy viewed as a neo-empiricism, descending legitimately from the British School, but avoiding the unhappy fate of Hume and Mill and pointing the way towards a constructive and adequate philosophy. I shall continue to divide empiricism, for this purpose, into two major and complementary ideas: the experimental theory of existential knowledge, and the experiential notion of essence. The experimental theory of knowledge is the theory that knowing initiates ideas of existence which it submits to existence, and which existence itself accepts or rejects in the events of sensation. The experiential notion of essence is the theory that existence shines in its own light, or reveals its native quality in certain authentic modes of immediate apprehension such as perception.

James's experimentalism, reflecting an early Darwinian influence, excludes from the beginning the view that mind is a passive receptivity to the external order.[19] On the contrary, he says, mind is active and inventive. But every cognitive project is on trial and bound to submit itself to fresh findings, no matter what other credentials it may possess.[20] It places itself at the mercy of specific fact which it cannot control. In forming and trying hypotheses the mind is not only active, but interested. It tries what it hopes is true. If it refused to trust its interests, it would believe nothing; for belief at the moment of its occurrence invariably exceeds the given facts. Since the subjective factor is unavoidable it should be consciously recognized, in order that the appropriate moral standards may be applied to it. There are important fields, such as religion, in which the sensational test is remote or impossible; and in these fields the moral test becomes peculiarly important. That even here, however, fact-finding takes precedence of faith is clear from the importance which James attaches to the empirical evidence for God and freedom. Thus James's fideism grows out of his empiricism. It is a corollary of the generalization of the experimental method, and compensates for the limitations of empirically verifiable knowledge, being in this role substituted for the alleged *a priori* certainties of the rationalistic schools.

The other half of James's empiricism is his experiential metaphysics or notion of essence. Experimentalism takes account of knowledge by concepts, that is to say, the beliefs of everyday life, together with the systematic conclu-

[19] "Spencer's Definition of Mind as Correspondence," 1878, *Collected Essays and Reviews*, pp. 43 sq.

[20] *Will to Believe*, Preface.

sions of science and philosophy. But such knowledge reflects, culminates in, and verifies itself by, knowledge of another sort, a knowledge in which existence reveals its nature directly. Experimentalism deals with the limits of this more authentic knowledge, and the methods of transcending them. Experientialism, on the other hand, deals with the richness of this sort of knowledge, above all with its inclusion of relations, for the alleged lack of which it has been condemned by opposing schools. James elaborates this general thesis with scrupulous attention to detail: in his nativistic theory of tri-dimensional space, his doctrine of the specious present as embracing temporal sequence, his identification of causal activity with a unique pattern or train of sensible data, and in his interpretation of the self's unity and reflexive consciousness in terms of a 'judging thought' that takes its place in the common stream. The traditional chasms which other schools left unbridged, are *filled* by James with a positive, experiential content. Mind and body are differences of external relation and context attaching to identical terms, which are given, but are in themselves neither mental nor bodily. Thought's reference to its transcendent object is translated into routes from the nearer to the remoter portions of the one experiential field, or into a feeling of the direction and destination of such routes. Thus, by the inclusion of experiences of tendency, meaning, and relatedness, by a recognition of the more elusive fringes, margins, and transitions that escape a coarser sensibility, or a naïve practicality, or an unconsciously artificial analysis – by such inclusion, the field of immediately apprehended particularity becomes a self-contained continuum which is qualified for the role of metaphysical reality.

Reality construed empirically as an experience-continuum has unity both of kind and of connexion. But it is none the less a plurality, and not only because there is a moral interest in thinking it so, or because a world that can be known piecemeal must be divisible in its nature – it is a plurality empirically. The relations by which the world perceivably holds together are *de facto* or adventitious, rather than necessary, relations. It is characteristic of the totality of existence, as empiricism finds it, that its parts compose and yield the whole, rather than that a prior whole manifests itself in predetermined parts. Such a world is subject to change initiated locally, as, for example, in the human will. It is not only a fluid, but a plastic world in which there is a third alternative to resignation and despair. Not being essentially indivisible it may be praised with discrimination where it is praiseworthy, and worshipped where it is divine.

This continuous field of given existence, as James depicts it, is far removed from the sensationalistic atomism of the classic empiricists. But it was intended none the less as a correction and amplification, not as an abandonment, of the older tradition. The earlier empiricists failed because they were not empirical enough; and through their failure empiricism became an acknowledgement of defeat. Towards the end of his career James made repeated

allusions to the metaphysics which he was about to write. He was not spared to accomplish his purpose with the technical rigour which he had intended. But in his final metaphysics, incomplete as he felt and acknowledged it to be, James saw the dawning realization of that hope which was the deepest and most persistent motive in his philosophizing. "Let empiricism," he said, "once become associated with religion, as hitherto, through some strange misunderstanding, it has been associated with irreligion, and I believe that a new era of religion as well as philosophy will be ready to begin."[21]

[21] *Pluralistic Universe*, p. 314.

THE PHILOSOPHY OF WILLIAM JAMES

John Dewey. "The Philosophy of William James." *Southern Review* 2.3 (Winter 1937): 447–461.

The Thought and Character of William James, by Ralph Barton Perry. Vol. 1, *Inheritance and Vocation*; Vol. 2, *Philosophy and Psychology*. Boston: Little, Brown, and Co., 1935.

The impression that I carry away from reading the record of the activities and connections of William James is that in respect to many-sidedness he is the most significant intellectual figure the United States has produced. There are those who surpass him in special points: Jefferson, for example, in depth and range of political thought, and Emerson in consistency and concentration of pure intellectual flame. But James seems all but unique in his variety of conjunctions with vital matters. As I reflect upon the full and ordered record which we owe to the thorough and intelligent art of Professor Perry.[1] I can think of but one aspect of human interest that is not expressed. There are no signs of concern with the spectacle of history. Yet this fact seems to be positive in import – an indication not of an insufficient but of an abundant sense of life, of life irrespective of chronology. One may say that he is intensely contemporary; *is* rather than *was*. For his contemporaneousness concerns not the incidents that make up the passing show but springs from the problems and predicaments in which mankind finds itself implicated under all skies at all times.

The story of William James is of enormous interest when it is viewed simply as an account of an extraordinarily gifted family. Dr. Perry has done well to devote one-fifth of the first volume to the father, Henry James, Sr. A commentator could profitably devote an entire review to this remarkable man and his equally remarkable ideas and associations. Putting heredity to one side, one can hardly form an adequate picture of the gift of William James for lucid and picturesque diction and of the unconstrained originality of his thinking, without some knowledge of the father and the way in which he ignored the intellectual conventionalities and respectabilities of his day. I

[1] The subtitle – "As revealed in unpublished correspondence and notes, together with his published writings" – is worth quoting in full.

should like to pause to dwell on the family environment in which the budding capacities of James were formed. The spontaneity of affection that held it permanently together is not only a complete refutation of the notion that genius is hard to live with but is a heartening picture of what domestic life is capable of being. The respect which each member of the family shows for the personality of every other member can hardly have failed to be an important factor in shaping the idea of the individual which, as we shall see, is fundamental in the philosophy of William James.

Throughout the volumes runs the current of the affection and admiration in which William James and his brother, the novelist, Henry James, Jr., held each other. And there are occasional glimpses of the other children, each of whom rose far above the commonplace and mediocre. The pages of William himself could be searched in vain to find criticism more penetrating, expressed in any more vivid way, than that of the sister Alice, directed toward William. "William expressed himself and his environment to perfection when he replied to my question about his house in Chocorua. 'Oh, it's the most delightful house you ever saw; it has fourteen doors, all opening outwards.' His brain isn't limited to fourteen, perhaps unfortunately." And when she said that he "could lend life and charm to a tread-mill," she stated precisely the feeling of everyone who enjoyed contact with the unconquerable vivacity of his interests; a persistent animation that was sustained throughout recurrent physical and mental ill-health. The novelist brother was constant in his affectionate admiration for his older brother, and while he had no interest in philosophy and professed incapacity for understanding it, he nevertheless put his finger upon the spirit of William's philosophizing when he wrote enthusiastically after the receipt of *Pragmatism* that its author had made philosophy more interesting and living than anyone had made it before, through creation of a philosophy that was "relevant and assimilable and referable."

The second part of Perry's work is entitled "Education and Career" and is a welcome substitute for what often passes as biography. For Perry permits the story to develop largely in terms of letters written by and to James, while he himself supplies just the quality and quantity of interpretive comment that is needed to make the story consecutive. Here too, as well as in family relations, there is a certain uniqueness of significance. William James had no schooling in the ordinary sense of that word. But he was exposed to an unusual variety of contacts, and most of them, unlike the themes of ordinary schooling, "took." His father had reacted strongly against the Calvinistic zeal of *his* father, expressed in desire to form his children in his own moral image. He wrote in an almost Rousseauan vein, "The great worth of one's childhood to his future manhood consists in its being a storehouse of innocent natural emotions and affections, based upon ignorance.... I am sure that the early development of my moral sense was in every way fatal to my natural innocence, the innocence essential to a free evolution of one's spiritual

character." In consequence, he withheld himself, to a degree extraordinary for his day and age, from the attempt to mould his children's beliefs and characters. At first sight this abstinence appears to conflict with the unusual depths of his personal convictions. In reality it is a tribute to the fidelity with which he lived up to his deepest conviction: the necessity of *free* evolution of spiritual character. The apparently haphazard nature of the education of the children and its actual issue in fruitful achievement cannot be understood apart from the loyalty of the father to his faith in human nature, when the latter is free from the distortions of convention and the paralysis of rigid institutionalism.

In an optimistic moment, he once wrote, "My sole hope for humanity is that men will go on more and more to such a complete obedience of their natural instincts that all our futile old rulers, civil and religious, will grow so bewildered as to abandon their thrones and leave the coast free to scientific men" – not that obedience to natural instinct was the desired goal but that it was a necessary condition of its attainment. The actual or practical result was finely summed up in the comment of the daughter Alice. "How grateful we ought to be that our excellent parents had threshed out all the ignoble superstitions, and did not feel it their duty to fill our minds with the dry husks – leaving them *tabulae rasae* to receive whatever stamp our individual experience was to give them, so that we had not the bore of wasting our energy in raking over and sweeping out the rubbish."

Not the least important factor in the education of William was his temporary and experimental adoption of the career of a painter. Apropos of the fact that he abandoned the career of artist in behalf of that of scientist and philosopher, while Henry fell by sheer force of temperament into that of literary artist, Mr. Perry makes one of the most discriminating of his many discriminating comments. Of Henry he says:

> Experience afforded patterns or *scenes*, having for him some mysterious affinity of order or rhythm by which they were apprehended feelingly as units, and by which they became possessions to be stored against the day of their literary use. William shared this passion, but though an insistent it was always a subordinate motive. His own proper and deeper passion was to look behind the scene for causes or to look beyond in behalf of governing purposes ... William had a painter's eye. He had a capacity, perhaps never equaled, of seizing and exposing the evanescent moments and fugitive sequences of conscious life.... But he never indulged this interest without a revulsion against it, a revulsion that took one or the other of two forms – either *action* or *explanation*.

Henry speaks of the "inveteracy of his [William's] interest in the 'queer' or the incalculable effect of things. There was apparently for him no possible

effect whatever that might not be more or less rejoiced in as such – all exclusive of its relation to other things than merely knowing." This aggressive catholicity of interest, with a bias, on the whole, in favor of the odd, involved an experimental attitude that was not congenial to the profession of painting, at least as that was pursued in the early sixties.

There seems to be no clear explanation of why he left painting save that it failed to hold him. His feeling that he could never be more than a mediocre painter appears to me to be but a translation of the fact that the art did not absorb him. Nor does there seem to have been, at the outset, a definite indication of a "call," as the religious people used to term it, to science. He had been interested from boyhood in experiments, chemical and electrical, and when the scales went down for art, the other pan went up for science. His upbringing as well as his temperament predisposed him to tentative search for a vocation rather than predestined him to a particular career. His movement from art to chemistry, from chemistry to medicine, on to physiology and to physiological psychology, and from that to psychology and to philosophy, and to philosophy of a progressively "metaphysical" cast, is the record of a mind and personality that was continuously striving to find itself. While external physical conditions, such as the weakness of his back that made prolonged laboratory work impossible, played a part in determining his choice, I can but think there is an intimate connection between his enduring search, through many turns and windings, for himself and his own potentialities, and that sense of an unfinished and still developing world that colors all his philosophizing.

However this may be, the path that took him through a variety of interests and pursuits assuredly enriched his store of knowledge, added cumulatively to his resources, and prevented that premature hardening which is perhaps the bane of most persons who follow philosophy professionally. Above all it extended his range of personal contacts and associations. It would take, I fancy, a page of print simply to list the names of persons with whom he had intellectual companionship and with whom he carried on a stimulating exchange. This wide acquaintance expressed his genius for friendship. A reader who should dip casually here and there into these large volumes might wonder whether at times letters of no great moment were not too extensively reproduced. But one who reads consecutively will, I am sure, come to the conclusion that nothing could well be spared. As with the painting of a portrait, the multiplication of strokes, many minute in themselves, build up a solid figure. A great debt of gratitude is due Mr. Perry for the skill and patience with which he has accomplished his task. The obligation extends far beyond the circle of professional psychologists and philosophers. The range of intellectual connections of William James was so wide and the fervor with which he went out to meet them so intense, that the volumes give an irreplaceable portrayal of a most significant aspect of the development of American culture in the last two-thirds of a century.

An account of William James as a philosopher cannot, then, be separated from the development of William James the man, as this development was influenced by his family relations, his informal but vital education, and his varied contacts with vocations and men. This fact is, indeed, the point which reading of these volumes has most impressed upon me. To my mind, William James constitutes a memorable turning point in the story of American philosophic thought precisely because the human man always took precedence of the professional philosopher. He says of himself, "I originally studied medicine in order to be a physiologist, but I drifted into psychology and philosophy from a sort of fatality. I never had any philosophical instruction. The first lecture on psychology I ever heard being the first I ever gave." It would be easy to exaggerate the element of "drift." A drift that occurs because of fatality is an impulsion from within, not a floating on an external current of chance. But the struggles of James within himself, the tardiness of his recognition as a genuine philosophic thinker, his final crucial influence in redirecting much of American philosophical thought, all of these things, in my opinion, have an intimate connection with the fact that he never underwent academic and professional philosophic instruction.

I do not mean, of course, that mere absence of such instruction is a warrant of philosophic independence and originality, or even a contributing factor. The contrary is the case. Self-taught philosophic "geniuses" usually exhibit lack of proportion and perspective, and exhibit swollen conceit of originality when they awkwardly reproduce some one or other of the most familiar of philosophic conceptions. James doubtless suffered at times from lack of the technique which is about all that formal philosophical instruction can confer. But his native gifts, his family environment, his range of contacts, combined with the instruction he obtained through his own studies, render in his case a defect of technique of slight import. His escape from the cramping influence of intellectual traditions, which in the hands of the average teacher are hardened into lifeless conventions, had something to do, in my opinion a great deal to do, with the intensity with which he laid hold of philosophical problems. As I have already intimated, they were for him first of all problems of urgent personal force and vitality; since they were not covered over by things learned at second hand, they retained the freshness and immediacy that are such striking factors of the thought of James, so striking as to make him all but unique among philosophers. To say these things does not imply lack of respect for technique. Original vision in order to endure and make its way must take on the resources afforded by competent technique. But there is always the danger that mastery of the tools of the intellectual trade will become a substitute for vision, while the inherent sincerity of an experience such as that of William James may be trusted in the end to generate its own relevant technique.

It is for this reason that I feel justified in including such remarks as I have made about the environment and career of William James under the general

caption of his *philosophy*. The philosophical writings of James have, to an unusual degree, their own luminosity. But the record of his correspondence and his otherwise unpublished notes take us behind the printed word; they bring us face to face with the generative experiences from which the written word is derived. I do not know of any other case in the whole available record of intellectual origins and development in which we are so fully taken behind the scenes and initiated into the vital personal experiences out of which formulated doctrines finally sprang. Interest in the initiation and the gratitude due Mr. Perry for making the record accessible are not confined to those especially occupied with philosophy. They are shared by all those interested in the history of American intellectual life and by all those who are concerned with the mysterious conditions that lie back of original creative productivity.

Before coming to what seems to be *the* problem that entered so deeply into the experience of James as to determine the structure of his philosophy (even accounting for certain features that taken by themselves seem eccentric), I want to quote some things that were said by James at various times about philosophy and the teaching of philosophy. James remarked, in a letter to Hobhouse, that every philosopher is motivated by some bogey in the background that he wants to destroy. The remark seems to me profoundly true; failure to realize what it is that a philosopher feels the pressure of and wants to get rid of is one of the main sources of the infertility of philosophical controversy. James goes on to add that *his* bogey is *dessication*. It is in this context that I would place remarks like the following, made about Wundt in the course of a letter to Stumpf.

> Surely, you must admit that since there must be professors in the world, Wundt is the most praiseworthy and never-too-much-to-be-respected type of the species ... a professor, a being whose duty is to know everything and to have his opinion about everything connected with his *Fach*. He says of each possible subject, "Here I must have an opinion. How many possible opinions are there? three? four? Yes, just four." Thus he acquires a complete assortment of opinions of his own and as his memory is good, he seldom forgets what they are.

I cannot but think that this passage throws, by contrast, a good deal of light upon the aims and procedure of James himself, including the things for which he has been most criticized – such as the inconsistencies of expression that are found because in dealing with one subject James forgets just what he has said upon some other occasion. His correspondent, the English thinker Shadworth Hodgson, expressed the characteristic quality of James with great moderation when he wrote that James "makes us see the reality of things, the real common-sense of the questions and problems at issue." When James Ward complained, in a review, complimentary on the whole, of James' lack

of systematic treatment of psychological topics, James replied admitting that he was too unsystematic, but added: "In this case I permitted myself to remain so *deliberately*, on account of the strong aversion with which I am filled for the humbugging pretense of exactitude in the way of definition of terms and descriptions of states that has prevailed in psychological literature." The conviction expressed in this remark is the reason why James at times seems to lean over backward in fear of system-making that is artificial, and it certainly helps explain his later overresponsive attitude to Bergson's attack on logic and conceptual constructions generally. The fact is, however, that much in James that was attacked by his early contemporaries as lack of sufficient respect for logical form is in reality an expression of his superior intellectual conscientiousness. He was keenly sensitive to the danger of forcing unity and system beyond what facts themselves indicated.

There is a reflection of his basic intellectual conscientiousness in the reasons that he gave, in accepting an instructorship in anatomy, for not taking up philosophy as a career – for he was quite aware even then that his chief interest was in philosophical or general problems. He draws back, he says, from adopting the career of a philosophic teacher, in spite of the fact that his deepest interest is in philosophic issues, because he is so constituted that he needs some stable reality upon which to lean, while "a professed philosopher pledges himself publicly never to have done with *doubt* on these [the fundamental] questions, but every day to be ready to criticize and call in question the grounds of his faith of the day before." There are, I suppose, many occupants of philosophic chairs who go through the form, as a matter of pedagogic technique, of such persistently renewed questioning. But it would be difficult, I think, to find cases where the sense of the obligation of the philosopher to be ready to carry out the doubts and questionings in good faith was so strong as to lead him so to doubt his own enduring strength to assume the responsibility that he was deterred from the career of the philosopher. It would be impossible, it seems to me, to find better evidence of the profound seriousness of James' sense of intellectual responsibility – a sense which his early critics, perhaps because of his occasional irrepressible levity of verbal expression, were loath to credit him with.

A few years later, while still teaching physiology, he uttered golden words as to what philosophy and its teaching should be. "Philosophic study means the habit of always seeing an alternative, of not taking the usual for granted, of making conventionalities fluid again, of imagining foreign states of mind.... What doctrines students take from their teachers are of little consequence provided they catch from them the living philosophic attitude of mind, the independent, personal look at the data of life and the eagerness to harmonize them." Although James is conventionally supposed to be opposed to unity and system on principle, he expressed one of the leading motifs of his life when he said that one can never be a great philosopher who lacks "that personal,

unitary, all-fusing point of view which the great ones have." What he objected to was the unitary point of view that is merely dialectical, not personal, and in which parts are externally held together by mechanical logic rather than fused in and by emotional and volitional conviction. Later when he had arrived at relative philosophic maturity he said of Royce's *World and Individual*, "The subject is not really vital to him, it is just fancy-work." When one recalls his genuine admiration for Royce's gifts in comparison with those of most other teachers of philosophy, one gets a glimpse of the gulf that separated his idea of what constitutes genuine philosophy from the academic practice frequently followed.

The justification for quoting at length these incidental comments is that they convey by contrast the vitally personal source of James' own philosophizing. I do not know any other modern thinker whose philosophy owes so little to dialectics and to tradition, to the second hand generally, and so much to predicaments that were vitally experienced; that in the large and proper sense of the word were moral in quality. In him the need for working out a viable philosophy was one with the need for finding a solution of matters that weighed heavily upon him as a living being. Mr. Perry justly emphasizes the importance attached by James to the motives from which philosophizing proceeds. I hope I do not do him injustice in saying that he would recommend James' essay on "The Sentiment of Rationality" in the form in which it included the essay on "Rationality, Activity and Faith" (together with James' own notes now made available) as the natural introduction to James' own philosophy. The needs to be satisfied are, on the theoretical side, clearness and unity. Their demands are so different as to tax thought to the uttermost. For clearness moves in the direction of diversity, the Many, while the simplicity that results from one-sided emphasis upon the One, is often specious. The incapacity of monistic systems to resist analysis from the standpoint of either fact or logic is one of James' favorite themes. But even when the conjoint need for unity and clarity is satisfied, we are only at the threshold of an adequate philosophical system. The practical needs of man, emotional and volitional, must also be satisfied. It is the depth with which James felt the urgency of the latter need that marked him off from most of his contemporaries, and that, as I have already suggested, explains both the early uncomprehending and often scornful rejection he experienced and the power of inspiration exhibited later by his thought.

There exists a letter written by James as early as 1869, the year in which he received his M.D., the time at which, probably, the influence of natural science was at its height with him, in which one finds the clue to the problem that was central in the formation of his own philosophy. After saying that there was once a period in which the ideas of nature and of human fate were conglomerated in one, he says that in their later development "the nature-lore and the individual-fate-lore or religion have become so differentiated as to be antagonistic."

The remark might be interpreted in the sense of the conventionally recognized conflict of science and religion, since nature-lore is so evidently a name for science. But such an interpretation misses the point. The identification of religion with "individual-fate-lore" and the feeling that the effect of science is to submerge, to deny, the importance of individuality and of what happens in and to the individual as such is the significant matter. It is significant both negatively and positively. The early environment and rearing of James had made it impossible for him to conceive of religion in the terms of any historic religion, even that of Christianity in its purest and most sublimated form. There is hardly a word in all of his numerous writings about religion, about either any special doctrine of Christianity or the figure of its reputed founder. Such allusions as he makes to churchly creeds and practices are, for him, unusually unsympathetic in tone. They are in the vein of the following:

> My training in natural science has completely disqualified me for sympathetic treatment of the ecclesiastic universe. It is impossible to believe that the same God who established nature should also feel a special pride at being more immediately represented by clergymen than by laymen, or find a sweet sound in church-phraseology and intonation, or a sweet savor in the distinction between deacons, archdeacons and bishops. He is not of that prim temper.

It is sometimes said that the essence of Protestant Christianity is the assertion of the immediate relation of God and the individual soul. With this conception as a basis, it may be said that James carried the spirit of Protestantism to a point where any connection with Christianity became meaningless. The "individual-fate-lore" in which he was interested was universal. All individuals looked alike to him as far as individuality is concerned in its relation to the universe. Hence the special treatment of religion that appears, say, in his *Varieties of Religious Experience* is but a part of his general philosophy and cannot be justly appreciated apart from the latter. On the face of the pages of that book, he selected cases so extreme that he himself called them pathological. But his selection was based on the belief that certain generic features in the relation of the individual as such to the universe were thrown into high relief in these cases, and could accordingly best be studied through them. The root idea is that in the religious experience, the essential individual – call it his soul – stands in communication with the universe at a level more primitive and at the same time more fundamental, in a certain way more veridical, than is attainable at the level of conscious and rational observation and thought. The result is "a kind of experience in which intellect, will and feeling, all our consciousness and all our subconsciousness together melt in a kind of chemical union." Hence every genuinely religious experience is that which for lack of a better name we call mystical. In this experience, the "less articulate but more

profound parts of our nature hold out against the attempt of a more superficial and loquacious part to suppress it." James was quite aware that this notion of the essentially irrational and instinctive origin of religious experiences was capable of being used as an argument against the validity and utility of religion. He himself deliberately chose to give the idea another and favorable interpretation. This choice roots partly in a temperamental feeling of the importance of vital instincts, on the ground that they represent the *process of life* more effectively than can rational thought, and partly springs from his philosophical doctrine that in any case immediate experience is more fundamental than are the ideational constructions built upon it. The underlying conception, I should say, is that the individual after all must have some vital connection with the universe in which he lives and that this connection can ultimately be but of two kinds. It is either such as to depress the individual or such as to support and invigorate him. Morally, we are entitled to adopt the latter attitude for the purpose of action even though rational proof of its validity be lacking. Short of the existence of overwhelming evidence of the invalidity of the belief, we may choose to live, to act, heroically, upon the assumption that something in the universe feeds our ideal aspirations and is actively on the side of their realization.

I have, then, dwelt at length upon the concern of James with religion and his understanding of its nature just because the latter is so different from what is usually called religion. The nub of the whole matter is the problem of the genuine relation of the individual and the universe, and this is the question which is final for philosophy itself. The growing opposition of James to monism in every form, idealistic as well as materialistic; his struggle against absolutisms of every sort, metaphysical, ethical, political; his pluralism; his indeterminism – all the determining *motifs* of his philosophy spring from his extraordinarily intense and personal feeling for the worth of the individual, combined, however, with an equally intense realization of the extent to which the findings of natural science (to which he was loyally devoted) seemed hostile to rational justification of the idea that individuality as such has any especial value of justification in the universal scheme of things. His long preoccupation with the philosophy of his colleague, Royce, vividly portrayed in the volumes before us, is a record of his dissatisfaction with the effort to give value to the individual on the basis of monistic idealism. As he once wrote, "Make the world a unit, and worship and abhorrence are equally one-sided and equally legitimate reactions." Treat the world as a plurality, and the difference between good and bad has a meaning, and because of this difference, choice, loyalty, adoration, have also a meaning. But James was equally unconvinced by the attempts of his chief fellow pluralists, Davidson and Howison, to find a strictly *rational* support for the doctrine of the primacy and ultimacy of individuals as such. Their views seemed to him to be, on one side, abstractly dialectical, and, on the other side, to be based on

lack either of adequate empirical and scientific knowledge or else of adequate respect for such knowledge (probably on both). A certain act of faith in the sense in which faith means the resolve to live as if a certain doctrine were true until evidence appears to the contrary, was to him the way out. Meantime, the act of faith has a *certain* amount of rational support in our instinctive emotional life and in the deliverances of immediate experience as a mode of acquaintance-knowledge.

The biographic roots of this basic philosophic attitude of James seem to be found, rather especially, in the crisis of his own life, that was undergone in connection with extreme depression due to ill-health, in 1870. He found the only promise of a way out in the assumption of a certain attitude of resolute action. The philosophical implications involved in this attitude are strangely prophetic of the most fundamental ideas of his later philosophy. He asked, in his diary, "Can one with full knowledge and sincerely ever bring himself so to sympathize with the *total process of the universe* as heartily to assent to the evils that seem inherent in its details? … If so optimism is possible." But the distinctive interests and sympathies of the individual may seem so important to him that they refuse to be swallowed up in the "feeling for the total process." In this case, the resulting attitude must be such hostility to the structure of the universe that pessimism is the only outcome. However, between the two extremes there is an alternative. "If a *divided* universe be a conception possible for his intellect to rest in, and at the same time he have vigor of will enough to look the universal death in the face, without blinking, he can lead the life of moralism." The conception of the intrinsic connection between a "divided" (pluralistic) universe and the attitude of resolute choice and action that is implicit in this passage, was reinforced as James came to see that certain volitional and emotional attitudes are the vital, although unexpressed, premises underlying both the optimistic monisms and the pessimistic dualisms that set the self and its interests in stark opposition to the cosmos as a whole.

The intensity of feeling that marks what James wrote in his diary and to his intimate friends in the time of crisis subsided as the years passed. But unless I have completely misunderstood the course of his development, as that is so skillfully and fully portrayed in the volumes before us, the sense of the problem involved remained basically the fountain-head of all his philosophy. It is at the root of his feeling of the conflict between science as nature-lore and religion as individual-fate-lore. It is the source not only of his pluralism and his indeterminism, but of his more special doctrines of the right to adopt in action a sincere belief in the absence of objective evidence and of that part of his pragmatism that emphasized that consequences, rather than origins, are the ultimate test and criterion of meaning and validity.

The sixth and final part of the present volumes is entitled "The Ultimate Philosophical System." Students of the metaphysical doctrine of James,

especially as regards the meaning of *Pure Experience*, will find much to assist them in these pages. If I forego further reference to them, it is not only because of limitations of space, but because I believe that the earlier exposition of the vital temperament and vital experiences of James is fundamental for the understanding of his more technical doctrines. The connection between the two becomes increasingly tenuous and indirect. But it is never lost. The sincerity and depth of the personal experiences which gave to James the key to the genuine meaning of philosophical issues remained the groundwork of his teaching. They are to my mind the enduring source of what we still have to learn from even the more technical aspects of his thought. In his attempts at developed formulation he was subject to the limitations from which every independent thinker suffers. The more original the thought, the more it is betrayed by the fact that the only language in which original insight can be expressed is that formed by the very doctrines against which one is reacting. Hence it is doubly important that the students of the philosophy of James never lose hold upon its vital springs and source.

THE VANISHING SUBJECT IN THE PSYCHOLOGY OF WILLIAM JAMES

John Dewey, "The Vanishing Subject in the Psychology of James." *Journal of Philosophy* 37.22 (24 October 1940): 589–599.

There is a double strain in the *Principles of Psychology* by William James. One strain is official acceptance of epistemological dualism. According to this view, the science of psychology centres about a *subject* which is "mental" just as physics centres about an *object* which is material. But James's analysis of special topics tends, on the contrary, to reduction of the subject to a vanishing point, save as "subject" is identified with the organism, the latter, moreover, having no existence save in interaction with environing conditions. According to the latter strain, subject and object do not stand for separate orders or kinds of existence but at most for certain distinctions made for a definite purpose *within* experience.

The first view is explicitly set forth by James in the following words:

> *The psychologist's attitude toward cognition* will be so important in the sequel that we must not leave it till it is made perfectly clear. *It is a thoroughgoing dualism*. It supposes two elements, mind knowing and thing known, and treats them as irreducible.... They just stand face to face in a common world, and one simply knows, or is known unto, its counterpart. This singular relation is not to be expressed in any lower terms, or translated into any more intelligible name.... Even in mere sense-impression the duplication of the object by an inner construction must take place.... The dualism of Object and Subject and their pre-established harmony are what the psychologist as such must assume, whatever ulterior monistic philosophy he may, as an individual who has the right also to be a metaphysician, have in reserve.[1]

The *Psychology* was published in 1890. Much of the book was written some years before. The material of the important chapter on the "Stream of

[1] *The Principles of Psychology*, Vol. I, pp. 218–220, passim. Italics in original text. Referred to hereafter as *Psychology*.

Consciousness," which verbally is probably the most subjectivistic part of the whole book, was published in *Mind* in 1884.[2] In 1904 in his article "Does 'Consciousness' Exist?" he says of the "consciousness," which the passage quoted takes as the basis and source of the material of his *Psychology*, that it is "mere echo, the faint rumor left behind by the disappearing 'soul' upon the air of philosophy." And what is especially significant for the present theme, the tendency of the separate subject as knower to disappear even in the *Psychology*, he adds "for twenty years past I have mistrusted 'consciousness' as an entity; for seven or eight years past I have suggested its non-existence to my students."[3] "Twenty years" takes his distrust well back of the date at which his *Psychology* appeared. A moderate amount of psychoanalysis might lead one to infer that the explicitness with which he states that the assumption of dualism is necessary for the psychologist means that he entertained doubt about the *ultimate* soundness of the dualistic position.

That he did not go further than he did go in his *Psychology* is not surprising in view of the state of the subject at the time he wrote. In view especially of the fact that he attacked both of the only two trends which then existed in psychology, namely, associationalist and "rational" psychology, one can understand why he hesitated to carry his scepticism to an even more radical extreme. For the only alternative to these two views that existed at that time was a dogmatic materialism with its "automaton" theory of psychological phenomena. In spite of the tenderness of James on the topic of the *soul* he wrote that there was no scientific need whatever for a substantial soul or permanent mind; he went so far as to give a strictly empirical account of personal identity.[4]

His reduction of the "subject" to a "passing Thought" is itself sufficient proof of the way he whittled down the knowing subject. And it is worth special note that in one passage, written in direct connection with his discussion of the Self, he goes so far as to express a doubt about the existence

[2] I say "verbally" because it is quite possible to translate "stream of consciousness" into "course of experience" and retain the substance of the chapter.

[3] Essay reprinted in *Essays in Radical Empiricism*, p. 2 and p. 3.

[4] For his tenderness see the *Principles of Psychology*, Vol. I, p. 181, where he says "The fact is that one cannot afford to despise any of these great traditional objects of belief." As to the substantial soul and permanent mind, see Vol. I, p. 346, where he says "As *psychologists*, we need not be metaphysical at all. The phenomena are enough, the passing Thought itself is the only *verifiable* thinker, and its empirical connection with the brain-process is the ultimate known law." As to personal identity, as evidence for a permanent substantial subject or self, he was influenced by the recently discovered facts of split personality and wrote (Vol. I, p. 350), "The definitively closed nature of our personal consciousness is probably an average statistical resultant of many conditions, but not an elementary force or fact."

of even a separate "thought" or mental state of any kind as the knower, saying that it might be held that "the existence of this thinker would be given to us rather as logical postulate than as that direct inner perception of spiritual activity which we naturally believe ourselves to have."[5] However, he dismisses this conclusion, although it is a direct result of his actual analysis, as "speculative" and says that speculations "contradict the fundamental assumption of *every* philosophic school. Spiritualists, transcendentalists, and empiricists alike admit in us a continual direct perception of the thinking activity in the concrete. However they may otherwise disagree, they vie with each other in the cordiality of their recognition of our *thoughts* as the one sort of existence which skepticism cannot touch" (pp. 304-305). But he adds in a footnote a remark that is especially significant in view of the article of 1904 to which reference has been made. For he says that there is one exception to the statement about all philosophical schools, namely, the important article of M. Souriau, the conclusion of which is "que la conscience n'existe pas." That James's own denial of the existence of consciousness involves a complete repudiation of the dualism earlier officially professed is obvious from the following words of his later essay in which he says what is denied is an "aboriginal stuff or quality of being, contrasted with that out of which material objects are made, out of which our thoughts of them are made."

Before taking up in detail the whittling down of the mental or psychical subject as it occurs in the *Psychology*, I shall say something about the position which, if it had been developed positively and in detail, would have rendered unnecessary from the start any reference even to the "passing thought" as that which remains from the old substantial subject. This position is suggested in the passage already quoted in which James refers to the brain process as "the ultimate known law." James came to the study of psychology from a grounding in physiology in connection with a preparatory medical education. His naturalistic strain, as far as constructively stated, and its conflict with the professed epistemological dualism, was derived from this source. If it had been consistently developed it would have resulted in a biological behavioristic account of psychological phenomena. In his first expression of opposition to both the "rational" and the "associational" psychologies, he says that certain deficiencies in both of them proceed from their inability to take into account obvious physiological facts which demand recognition of the organism and the nervous system. He goes on to say that the Spencerian formula according to which biological and psychological phenomena are one in essence, both being adjustments of "inner" to "outer" relations, while very vague, is immensely more fertile than the old-fashioned rational psychology "because it takes into account the fact that minds inhabit environments which act on

[5] *Principles of Psychology*, Vol. I, p. 304.

them and on which they in turn react."[6] On this side, James's fundamental doctrine is that psychological phenomena (called by him the *mental life*) are intermediate between impressions received from the environment and the responsive adjustments the organism makes to the environment. If what is involved in this view had been consistently maintained, the dualism that existed in Spencer's two sets of "inner" and "outer" relations would have been overcome, and organisms or personal beings, not "minds," would have been said to "inhabit the environment." The behavioral position is maintained when James says that "pursuance of future ends and choice of means for their attainment are the mark and criterion of presence of mentality in a phenomenon," since the passage suggests that the whole meaning of *mentality* consists in objectively observable facts of the kind mentioned. But as the matter is finally left it may be doubted whether James intended to go further than to say that this pursuance and choice is the external sign of something called "mental" operating behind. For he limits the scope of the statement by saying that the view just stated would be adopted as the mark and criterion by which to circumscribe the subject-matter of this work *as far as action enters in*.[7] The clause I have italicized indicates that he held to the existence of phenomena so "mental" in nature that action (behavior) does not enter into them. At the same time, the position of James is free from that defect of the latter "behaviorism" which locates behavior, and hence psychological phenomena, *inside* the organism. For he says that the function of the nervous system "is to bring each part into harmonious co-operation with every other" part so as to make possible acts which are of service in connection with the sensory impressions proceeding from the environment.[8]

Since the biological approach does not control subsequent analyses to the extent that the introductory chapters would by themselves have led one to expect, it is worth while to note instances in which it is definitely influential. The chief cases are the treatment of habit and the effect of practice. The former, treated as a biological factor having its basis in the constitution of matter, is said to be the "cause" of "association of ideas," and hence of retention and recollection, and also of imagination.[9] Even more significant in its implications (which, however, are not developed) is his statement that "attention and effort ... seem in some degree subject to the law of habit, which is a material law."[10] The operation of practice, understood in terms of motor

activities, is made central in discrimination. "Where ... a distinction has no practical interest, where we gain nothing by analyzing a feature from out of the compound total of which it forms a part, we contract a habit of leaving it unnoticed."[11] He makes a great deal of Helmholtz's view that we notice "sensations" not *per se* but as "far as they enable us to judge rightly of the world about us; and our practice in discriminating between them usually goes only just far enough to meet this end" (p. 517). The ambiguity, noted later, between "sensation" as a strictly physiological process in the afferent structures and as a perceived quality of an object, influences James's treatment, since he seems to assume that the "sensation" is there all the time but I sometimes noted and sometimes not—a position all the more surprising because of his elaborate criticism of the doctrine of "unconscious mental states." He uses such expressions as the following: "Helmholtz's law is that we leave all impressions unnoticed which are valueless to us as signs by which to *discriminate things*. At most such impressions fuse with their consorts into an aggregate effect." Only the influence of an inveterate dualism could lead James to call sensory processes "impressions."

The later pragmatism of James is implicit in what he says about reflective thinking or reasoning. "My thinking is first and last and always for the sake of doing, and I can only do one thing at a time." There are no "truer ways of conceiving [understanding or interpreting]" things than any others; there are "only more important ways; more frequently serviceable ways."[12] Finally, in contrast with the current theory of perception, James gives an account which is definitely biological and behavioral.

> We certainly ought not to say what usually is said by psychologists, and treat the perception as a sum of distinct psychic entities, the present sensation namely, *plus* a lot of images from the past, all "integrated" together in a way impossible to describe.

The simple and natural description is

> that the process aroused in the sense-organ has shot into various paths which habit has already organized in the hemispheres, and that instead

[11] *Ibid*., pp. 515–516.

[12] Vol. II, pp. 333–336. On page 335 we read the following: "The essence of a thing is that one of its properties which is so *important for my interests* that in comparison with it I may neglect the rest." The important role of "interest" in the entire scheme of James's account of psychological phenomena is a well-known fact. Officially he assumes interest to be mentalistic. What he actually says about it is most readily understood in terms of the selections effected by motor factors in behavior.

> of our having the sort of consciousness [perception] which would be correlated with the simple sensorial process, we have that which is correlated with this more complex process.[13]

When we ask why James did not develop his treatment in the direction indicated by these considerations, we come back to the influence exercised by the surviving metaphysical dualism. For as long as this dualism is postulated, the connection the nervous system, including the brain, indubitably has with psychological phenomena is a "mystery," and the more detailed and complete the evidence for the connection the more the mystery deepens. The influence of the dualism is so strong that James does not follow out the implication of his hypothesis that the brain—and nervous system generally—functions as an organ in the behavior constituted by interaction of organism and environment. Consequently, instead of applying the idea to the description of each one of the diversity of observed psychological occurrences, showing how it links up in detail with the general doctrine of the function of the nervous system as an instrumentality of effective interaction of organism and environment, he goes so far as to express adherence to the most miraculous of all the theories about the "mystery," namely, the parallelism or pre-established harmony of physical and psychical.

There is indeed a problem. But it can be broken down into a large number of things to be investigated. It is not a wholesale metaphysical problem, but a special problem like that of any scientific inquiry: namely, the problem of discovering the conditions of the occurrence of an observed phenomenon. Certain experienced situations occur, some of them mainly emotive or affectional in quality; others that of knowledge of this or that thing. The question of how these experienced situations come into existence is important because knowledge of conditions is always a prerequisite of control. Knowledge of organic conditions is part of the knowledge required if having of desired experiences and not having of unwanted experiences is to come under our control, knowledge of environing conditions being, of course, the other part. Knowledge of processes in the nervous system and brain is an important, although far from exclusive, part of the required knowledge of organic conditions. But in principle there is no difference between discovering the cerebral conditions involved in a hallucinatory or a veridical perception and the chemical conditions involved in occurrence of water. The difference is one of greater complexity. But our comparative ignorance of concrete conditions in the case of situations, as matters of experience, does not make a "mystery" out of them.

[13] *Ibid.*, Vol. II, pp. 80 and 79; cf. pp. 103–104.

I now come to discussion of some psychological matters where James admits that the duplication in an "inner construction" of what is experienced is no part of the fact which is observed, but is a later theoretical interpretation. In the passage about dualism, quoted at the outset, James says that this duplication is demanded even in the case of "mere sense impression." In his chapter on sensation James says:

> *A pure sensation is an abstraction*; and when we adults talk of our "sensations" we mean one of two things: either *certain objects*, namely, simple *qualities or attributes*, like *hard, hot, pain*; or else those of our thoughts in which acquaintance with these objects is least combined with knowledge about the relations of them to other things.[14]

The latter part of this sentence retains the reference to the inner "thought" as that which knows its outer counterpart. But James's sense for empirical fact caused him to recognize that in the actual experience of qualities as objects no reduplication in inner sensations is to be found. For immediately afterward he says:

> *The first sensation which an infant gets is for him* the Universe.... The infant encounters an object in which (though it be given in a pure sensation) all the "categories of the understanding" are contained.... Here the young knower [the infant, not a mental state] meets and greets his world. (P. 8.)

This position about sensory qualities is the one in line with the objective stand he takes whenever guided by evidence into the particular issue with which he is dealing.[15] The following passages are representative:

> Take the example of an altogether unprecedented experience, such as a new taste in the throat. Is it a subjective quality of feeling, or an objective quality felt? You do not even ask the question at this point. It is simply *that taste*. But if a doctor hears you describe it, and says: "Ha! now you know what *heartburn* is," then it becomes a quality already existent *extra mentem tuam* which you in turn have come upon and learned. The first spaces, times, things, qualities, experienced by the child probably appear,

[14] *Principles of Psychology*, Vol. II, p. 3.

[15] There is nothing intrinsically *sensory* about *red*, *hot*, *pain*. They are so named because experience has shown the importance of the organic apparatus by which they are mediated. That color is visual and sound auditory is an item of knowledge gained through study of the conditions of the *occurrence* of the quality; it is no part of the quality.

> like the first heartburn, in this absolute way, as simple *beings*, neither in nor out of thought.[16]

This view is probably the germ of his later theory of "neutral entities." The direct empirical meaning of *neutral* in this connection would seem to be that of indifference to the distinction between subjective and objective, this distinction arising when the proper guidance of behavior requires that we be able to tell whether a given sound or color is a sign of an environing object or of some process within the organism. Unfortunately his later writings seem at times to give the impression that these entities are a kind of stuff out of which both the subjective and objective are made—instead of the distinction being a question of the kind of object to which a quality is *referred*. If the latter position is taken then one of the problems of the psychologist is to determine the conditions under which a given *reference* occurs, the question of proper reference being the same *kind* of question that comes up when we inquire whether a given sound is produced by gunshot or by backfiring of an automobile.

Again, James says that "experience, from the very first, presents us with concreted objects, vaguely continuous with the rest of the world which envelops them in space and time, and potentially divisible into inward elements and parts." This passage is meant to apply to primitive as well as to highly elaborated experience of objects. For in the same context he speaks of "sensible totals ... subdivided by discriminative attention."[17] In another place he writes "No one ever had a simple sensation by itself. Consciousness [experience], from our natal day, is a teeming multiplicity of objects and relations and what we call simple sensations [qualities] are results of discriminative attention, pushed often to a very high degree."[18] Surely such passages as these indicate what is intended when it is said that the child's first sensation (experience) is for him the Universe, and that the "Universe which he later comes to know is nothing but an amplification and an implication of that first simple germ."[19] To hold that there is at the same time inner reduplication in thought or feeling is a case of what James elsewhere calls the psychologist's fallacy, reading into the original experience an inferential conclusion which the psychologist arrives at in his special investigations—in this case a wrong inferential result.

I now come to the central case in which the issue is clinched—the account given by James of the nature of the self and our consciousness of it, in which

[16] Vol. I, p. 272.

[17] Vol. I, p. 487.

[18] Vol. I, p. 224.

[19] Vol. II, p. 8.

the "subject" of dualistic epistemology disappears and its place is taken by an empirical and behavioral self. In speaking of the nature of "self-love" or egoism, he wrote:

> *The words* ME, *then, and* SELF, *so far as they arouse feeling and connote emotional worth, are* OBJECTIVE designations, meaning ALL THE THINGS *which have the power to produce in a stream of consciousness excitement of a certain peculiar sort*.[20]
>
> This position is developed in detail in connection with the bodily or material and the social selves which he has mentioned earlier. The general or theoretical position is that
>
> To have a self that I can *care for*, nature must first present me with some *object* interesting enough to make me instinctively wish to appropriate it for its *own* sake.
>
> What happens to them [our bodies] excites in us emotions and tendencies to action more energetic and habitual than any which are excited by other portions of the "field."
>
> My *social* self-love, my interest in the images other men have framed of me, is also an interest in a set of objects external to my thought.[21]

James, however, had postulated what he calls a "spiritual" self in addition to material and social selves. It might then well seem as if this psychical self, consisting of acts of choosing, consenting, refusing, and emotions like fearing, hoping, etc., remained *the* inner self, as an inexpugnable object of direct observation. But in fact it is in dealing with this aspect of the self that James puts forth his most explicit and detailed biological interpretation. For he says all that he can directly and empirically observe shows that this "'Self of selves,'

[20] *Ibid*., Vol. I, p. 319. The dualism is verbally retained in the mention of the "stream of consciousness." But aside from the fact that no difference is made in the argument when we substitute the words "the ongoing course of experienced things," the self or person is here expressly defined in objective terms, the small capitals being in the original text.

[21] Vol. I, pp. 319–321. Cf. the following: "The fact remains ... that certain special sorts of thing tend primordially to possess this interest, and form the *natural* me. But all these things are *objects*" (p. 325). The discussion of the special topic of egoism is an amplification of the earlier statement that a man's self is "*the sum total of all that he* CAN *call his*," all the objects he appropriates through the medium of a positive interest (Vol. I, p. 291).

when carefully examined, is found to consist mainly of the collection of these peculiar motions in the head or between the head and the throat."[22] In the context "these peculiar motions" are said to be "a fluctuating play of pressures, convergences, divergences, and accommodations in my eyeballs," and "the opening and closing of the glottis," with "contractions in the jaw-muscles" and the chest. These bodily movements, which are all that is directly experienced as the innermost centre, the "sanctuary within the citadel" of the self, are expressions of "a constant play of furtherances and hindrances, of checks and releases, of tendencies that run with desire and that run the other way." The theoretical interpretation is expressly stated in the following words:

> The nuclear part of the Self ... would be a collection of activities physiologically in no essential way different from the overt acts themselves. If we divide all possible physiological acts into *adjustments* and *executions*, the nuclear self would be the adjustments collectively considered; and the less intimate, more shifting self, so far as it was active, would be the executions. (Ibid., p. 302.)

He then says, since the adjustment activities are "entirely unimportant and uninteresting except through their uses in furthering or inhibiting the presence of various things, and actions," it is not surprising they are commonly overlooked. But the fact that adjustment activities are involved in all interactions with environing conditions, save in the acts that are most routine and "automatic," confers upon them a certain special position, for "they are the permanent core of turnings-towards and turningsfrom, of yieldings and arrests, which naturally seem central and interior."[23]

What is further said about personal identity is consistent with this behavioral interpretation. The appropriations of the passing thought are "less to *itself* than to the most intimately felt *part of its present Object, the body, and the central adjustments*, which accompany the act of thinking, in the head."[24] Furthermore, the belief in the sameness of the self arises on empirical grounds in the same way as belief in the sameness of any object whatever, "*the sense of our own personal identity*" being "*exactly like any one of our other perceptions of sameness among phenomena*."[25] Nevertheless the dualism reappears, for he still assumes that a "passing thought" must be there as the

[22] Vol. I, p. 301.

[23] Vol. I, p. 302.

[24] Vol. I, p. 341.

[25] Vol. I, p. 334.

knowing subject. Hence, after recurring to his doctrine that "'perishing' pulses of thought" are what know, he makes what on the face of it looks like an extraordinary compromise between the "pulse of thought" as *I* and the "empirical person" as *Me*.[26]

Were it important to do so, more evidence could be cited for the proposition that there are two incompatible strains in the Jamesian psychology, and that the conflict between them is most marked in the case of the self. But there is also evidence that on the side of the empirical strain there are the elements needed for a behavioral theory of the self. What he finally said in 1904, after he had thrown over his knowing Thought or Consciousness as a mere echo of a departed soul, was, after all, but an expression of ideas put forth in his *Psychology*, freed from hesitation and ambiguity. There is "the elementary activity involved in the mere *that* of experience,... and the farther specification of this *something* into two *whats*, an activity felt as 'ours' and an activity ascribed to objects." The former, he goes on to say, is

> part ... of the world experienced. The world experienced ... comes at all times with our body as its centre, centre of vision, centre of action, centre of interest.... The body is the storm centre, the origin of co-ordinates, the constant place of stress in all that experience-train.... The word "I," then, is primarily a noun of position, just like "this" and "here."[27]

But, as I have already intimated, he never reworked his *Psychology* so that all phases and aspects of psychological phenomena were observed and reported from this point of view. In consequence psychological theory is still the bulwark for all doctrines that assume independent and separate "mind" and "world" set over against each other. The idea originally came into psychology from philosophy. But now it is advanced by philosophers as having the warrant of psychology and hence possessed of the authority of one of the positive sciences. Philosophy will not be emancipated to perform its own task and function until psychology is purged, as a whole and in all its special topics, of the last remnant of the traditional dualism. And the purge requires more than a statement nominally made in terms of the living organism but in fact simply carrying over to the body distinctions that originated when there was a current belief in mind (or in consciousness) as a distinctive entity. This importation occurs whenever the phenomena are described in terms of the organism exclusively instead of as aspects and functions of the interactivity of organism and environment.

INTRODUCTION

Our Faith in the Work of History

The term "pragmatism" encompasses a lot more territory than is often appreciated today in scholarly circles. There is both an advantage and a danger in allowing the term to coalesce, as it has, around the meanings given to it by the thinkers whose ideas have stood the test of time, in this case, we speak of Charles S. Peirce, William James, and John Dewey.

> The advantage derives from our confidence that history sorts out for us the voices and ideas that are most worthy of our continued consideration. This confidence is often well placed. Those views do survive, most often, whose defenders have been the ablest, and in the case of "pragmatism," I do not dispute the judgment of history. Peirce, James and Dewey represent three very different conceptions of philosophical pragmatism, all defensible today, all still very much a part of the on-going development of philosophical thinking, and all showing different excellences towards which pragmatic thinking can tend. Each of these conceptions of pragmatism continues to enrich us, and the interplay among these views remains a source of new variations in our thinking.

The disadvantage comes in a small way from the possibility that genuinely valuable directions and meanings will come to be forgotten when history's judgment is imperfect, due to any of a thousand types of historical accident of timing, trend, tides of popularity, and the like. But the greater source of disadvantage comes from our tendency towards an occluded view of the major trends in which we fail to understand fully the push and pull against which those ideas were formed. So, for example, we may and often do fail to understand fully Dewey's or James's own sense of "pragmatism" when we remain ignorant of the dialogue against which and within which those senses were formed. Thus, to give a common example, the interpreters and defenders of James who have not closely studied Josiah Royce (1855–1916) remain ignorant of something they desperately need to understand. They will not grasp what motivates much of what James says about pragmatism, why he makes the moves he makes, unless they see the extent to which Royce's criticisms are pressing James's thinking, placing before him alternatives, and forcing him in some cases either to choose or to shift ground.

In the case of Royce, this problem is also especially acute among those who study Peirce. Royce was a figure very much at the center of the development of pragmatism, and who certainly regarded himself as a pragmatist. Long before this tendency in philosophy had the name "pragmatism," Royce was among the small handful of eminent philosophers working to develop it. For Royce, as for some of the others of that generation, such as Borden Parker Bowne, the arrival of the label "pragmatism" was not an event of any remarkable moment. Insofar as the label designated something worth considering, a practical turn in philosophy, a recognition of the role of practical consequences in the further conduct of philosophical thinking, it was something they had embraced many years before. The label itself was rather more like the advent of a new problem in philosophical nomenclature than the sudden birth of a new trend in thinking (the subtitle of James's 1907 *Pragmatism* indicates as much: "A New Name for Some Old Ways of Thinking"). And the problem with nomenclature became a serious distraction from the genuine issues at stake. The popularity of the label itself presented a temptation among philosophers to climb aboard the bandwagon without waiting to sort out the precise role of this tendency in philosophical thinking. In this case, the bandwagon itself certainly belonged to William James, and Peirce rather quickly decided he did not want to ride. Dewey stayed aboard a while longer, and when James died, Dewey seems to have taken the reins. In the first and second decades of the twentieth century, so much was written about pragmatism, both pro and con, that it became impossible to tell who was on whose wagon, and how many wagons there were, and who was driving any of them. A. O. Lovejoy's summary indictment of the movement in his "Thirteen Pragmatisms" nicely depicts the confusion.

In the chaos, two of the important voices that were lost to subsequent scholars were those of Royce and his student John Elof Boodin. Our understanding of pragmatism has been grievously diminished by this loss. It is well that the present volume may go some ways towards restoring what was lost, although in a world filled with other things to read, it is too much to hope that most pragmatists will pause over this long enough to reclaim this bit of context that could render them such fine service. Yet, we should let historical faith have some room to work, so perhaps we have here made a beginning towards reaching a fuller understanding of pragmatism. Let us briefly examine the pragmatism of Royce and that of Boodin and leave the rest to faith.

Royce's Pragmatism

This is not the place for a full scale assessment of the extent to which Royce might be called a "pragmatist,' although a tremendous amount of work has been done on this topic already by, among others, Frank M. Oppenheim.[1]

[1] Oppenheim's numerous writings on Royce would not be easy to list, but concerning this

What is wanted here is a summary of Royce's commitment to pragmatism and a sense of what he took it to be. Pragmatism can be summarized as involving the following key ideas:

1. a commitment to the primacy of *experience* as the source and the final test of the value of philosophical reflection;

2. that philosophical reflection is a kind of critical problem-solving activity that needs to take its impetus from genuine (as opposed to hyperbolic) doubt;

3. that truth is understood in light of the way it addresses problems and genuine doubt in practice;

4. that practice and practical consequences are the measure of the value of philosophy, not vice-versa.

This is admittedly over-simplified, but it is enough to help us grasp Royce's pragmatism. Regarding the first of these, consider the following from Royce's 1895 address "The Conception of God":

> All that we know or can know ... must first be indicated to us through our experience. Without experience, without the element of brute fact thrust upon us in immediate feeling, there is no knowledge.... I absolutely accept this view. This is true and there is no escape from the fact. Apart from – that is, in divorce from – experience, there is no knowledge. And we come to know only what experience has first indicated to us. I willingly insist that philosophy and life must join hands in asserting this truth.[2]

The primacy of experience does not, for Royce mean simply, as with Kant, that we cannot philosophize in the absence of experience in general. Royce insists rather that *particular* experience is the source of all knowing, and that what is known is never without its contextual dependence upon particular experience. There is no "experience in general," but only the further clarification of practical experiences that accumulate as the history of the individual

question of his relationship to pragmatism, they culminate in his colossal study, *Reverence for the Relations of Life: Re-imagining Pragmatism via Josiah Royce's Interactions with Peirce, James and Dewey* (Notre Dame, Ind.: University of Notre Dame Press, 2004). So thorough is this study that it leaves one little to say by way of addition.

[2] Josiah Royce, *Basic Writings*, ed. John J. McDermott, 2 vols. (New York: Fordham University, Press, 2005), vol. 1, pp. 363–364.

grows. Royce means by "experience" approximately what Dewey and James mean by it, and all of them are in some way or another beholden to Peirce's articulation of the question. The primacy of immediate feeling and the elucidation or generalization of feeling into concept is the shared conviction of pragmatists, including Royce. Differences begin to appear when we consider both *how* feeling becomes concept, and in the extent to which the resultant concepts can be trusted in terms of warranting our conclusions, especially our philosophical conclusions. In this domain, we can think of Royce as the most sanguine of the pragmatists, the one who places the greatest confidence in the scope of philosophical conclusions to provide us with a sort of warrant that justifies our claim to possess philosophical "knowledge," although Peirce is plenty optimistic, Dewey less so, and James might be thought of as allowing to philosophy the slightest degree of generalization of its conclusions.

The continuum of views here is reflective not only of the temperaments of each thinker, and perhaps also the degree of their commitment to radical empiricism, but also the extent of their respective commitments to the role and function of the a priori in addressing the practical life (which is the functional inverse of radical empiricism). The more a thinker tends to focus upon the peculiarities and accompanying complexities of a particular problem in relation to its own context, the less likely he is to give broad scope to any generalization of its solution to other contexts. Also the degree of genuine doubt, as the response to a problem, becomes a measure of the importance of the problem itself – the more pressing is the doubt, the greater the problem. And here is where differences in temperament begin to become differences in the estimation of the power and value of pragmatism and of philosophical knowledge in general. All pragmatists agree that the type of thinking called forth by practical problems is a substitute for action, and that when action is taken, thinking has been completed. All pragmatists agree that where the action taken proves inadequate to solving the problem, we will withhold our affirmation that a "true" solution has been found. But regarding the relationship between action and thinking there is a world of *territory* – the place where psychology and philosophy meets. Alternatively, where the solution proposed by our thinking *succeeds*, there is another wide range of possibilities for its generalization, and this is a second *territory*.

But these two territories, these types of pragmatism, fare differently in the hands of the dominant pragmatists. Where psychology and philosophy meet, where the task is to explain in empirically responsible ways, the process by which feeling or immediate experience becomes concept, Dewey and James have held a great advantage. Not only were both of them more accomplished psychologists than Peirce and Royce, but the growing tendency in the twentieth century to place greater confidence in this aspect of knowing (precisely because it was more easily studied by scientific and other empirical methods than the second territory, i.e., how to generalize successful hypotheses) has tended to

elevate the Dewey/James type of pragmatism to the place of honor. Indeed, their brand of pragmatism has effectively crowded out all other senses of the term. This result is not entirely to be despised, because after all, the process by which our concrete problems become our conceptual problems bears mightily upon our prospects both for understanding them and solving them. But our historical emphasis upon this territory, while it has yielded increasingly refined ideas about social epistemology, has distracted us from the second territory and has occluded our sense of the full range of "philosophical" responsibility. For it is in this second territory, the effort to understand the relationship between a successful course of action and its proper generalization to other contexts, that issues of value, imagination, vision, and ideals resides. The Dewey/James pragmatism is notoriously weak in dealing with this side of the matter, while this is the very strength of the Royce/Peirce variety of pragmatism. Let us pause over consideration of these idealistic versions of pragmatism to understand better how they operate.

The difference between the radical-empirical pragmatism and the more idealistic pragmatism emerges most pointedly from cases in which the "problem" is primarily intellectual from the start, and the genuine doubt it inspires is intellectual doubt. Here, Peirce and Royce will employ a priori thinking, especially the *reductio ad absurdum*, and without hesitation generalize the results to other intellectual problems, especially philosophical problems. Success in addressing an intellectual problem gets the advantage of having used intellectual tools (logic, mathematics, dialectic), and since these tools are already conceptual, their proper adaptation to other intellectual contexts is something that can be safeguarded by a thorough grasp of method. So long as one does not enter a hypothesis that works at cross purposes with some other generalization previously made, and so long as one discharges all hypotheses before hopping from one level of abstraction to another, the results of a good deductive argument can be employed in new intellectual contexts.

Dewey and James are quite hesitant about this, not wanting to distinguish in any way that requires final commitment between intellectual and practical problems. This certainly protects them from making illicit moves in dealing with intellectual problems, but it also commits them to reinventing and re-justifying all their conceptual tools for the purposes of each new problem. In other words, the Dewey/James pragmatism is ponderous and unwieldy in dealing with very abstract problems, such as those one would associate with metaphysics. And, the Dewey/James pragmatism also offers almost no hope for intellectual advance in such subjects as pure logic or in any domain of thinking that requires the development of new logical tools for handling other types of intellectual problems (beyond philosophy itself). So while Royce and Peirce were hard at work on the logic of relatives, Dewey and James remained fairly silent. This silence is not so great a problem until one enters the domain of metaphysics, a domain in which even radical-empirical pragmatists need some

footing in order to offer some account of the value and role of ideals in setting out an ethics and a political philosophy. Here, Peirce and Royce have far better tools, although Peirce makes little use of them. Unsurprisingly, each of them was far better at metaphysics than James and Dewey, and with a solid metaphysics in place, ethics and political philosophy become more manageable, less ad hoc, and more inspiring.

So pragmatists begin to diverge over the relative independence of intellectual problems from practical ones, and the fruit of this divergence is harvested in how to handle problems that require some independence from present context (the problematic situation, concretely expressed), especially the role and existence of ideals in informing our present problems. This divergence results in differing conceptions of the scope of philosophy itself. While Peirce and Royce tend to see philosophy as a fairly restricted kind of reflection upon certain kinds of problems that are *already* conceptual in character, Dewey and James want to include the process of conceptualizing the problem as one of the practical aspects of philosophy itself. While Royce and Peirce will insist that the philosophical problem already comes in conceptualized terms, and that philosophy can assist us in re-conceptualizing it, and that this work is as much a priori as empirical, Dewey and James are leery of this move. While ideals are therefore treated as concrete concepts by Royce and Peirce, they are bloodless abstractions in James's estimation, and promissory notes in Dewey's view.

So the question comes down to whether a pragmatist can afford to entertain ideals, and reason upon them in metaphysical and logical fashion, without ceasing thereby to be a pragmatist. Naturally, all pragmatists retain a place for ideals in their philosophies, but how binding our reasoning upon them is, how determinate they are, how concrete, here there is great disagreement. Royce tends to follow Peirce in his estimation of what makes a concept "true," and it involves giving philosophy a broad authority to make judgments upon various formulations of ideals, and the formation of purposes, using a priori methods. Thus, Peirce and Royce are not only not averse to teleological philosophy, they think it an absolute requirement of good philosophy. Dewey and James allow philosophy no such authority, even over its *own* problems, and will not embrace teleological language in any but the most provisional ways.

The cash value of this difference? Whether today one ought to favor the radical-empirical pragmatism over the idealistic type in matters of value remains unclear, but certainly we are aware, with this much time and distance, that the inability of the radical-empirical pragmatism to articulate a vision of ideals that inspires the moral admiration of philosophers and ordinary people is one of the red marks on its side of the philosophical ledger of the twentieth century. The idealistic sort of pragmatism has not really had its audit at this point, for it has passed into trust without ever having its capital spent. Royce's nascent re-emergence into philosophical prominence may provide that opportunity for entrepreneurs who are willing to risk the investment, or perhaps it will remain

in trust until another generation is heir to it. Much of what needs a new consideration is contained in this volume, but readers should be aware that there is far more in Royce than this volume contains.

Boodin's Pragmatism

In to this very breach between the radical-empirical pragmatism and the idealistic pragmatism stepped John Elof Boodin (1869–1950). Boodin was at Harvard from 1897 to 1900, and was influenced about equally by James and Royce. He was extra-ordinarily sensitive to both the similarities of their views and the differences, and in many ways his life's work can be read as an effort to reconcile what each had right. Boodin is certainly not the only Harvard product who attempted this synthesis – William Ernest Hocking and George Herbert Mead come immediately to mind as other distinguished synthesizers. But Boodin was probably the most balanced and indeed, in my judgment, the best at balancing the competing claims without sacrificing anything true. Boodin had a talent for metaphysics that Dewey and James lacked, and while he was not the logician that Peirce or Royce was, he was far more adept with it than James or Dewey. Boodin also had tremendous patience with the interpretation of empirical data, surpassing the patience of Royce, if not quite equaling the patience of James. Of course, Peirce was enormously patient with nature, but less so with people. Boodin was a better writer than any of the four major pragmatists, including James, and this makes Boodin's work pleasant to encounter. In what follows I will restrict myself to discussion of those aspects of Boodin's thought most relevant to pragmatism.[3]

Boodin's work encompasses a number of books, and because it is practically unknown today, I will make an effort to summarize the whole gist of his thinking in the remainder of this introduction so that readers can better contextualize the excerpts presented here. Most of these excerpts come from Boodin's 1911 book *Truth and Reality*, and this is indeed a programmatic statement of the books that were to follow as Boodin built his system of thought. Let me therefore speak of "truth" and "reality," in reverse order.

Reality. Boodin articulates an original version of Royce's "Fourth Conception of Being." Royce had argued in *The World and the Individual*[4] that there were really four historical conceptions of Being in philosophy, four general senses in which philosophers say "it is": *realism* (to be is to be

[3] For a more complete summary of all the major elements of Boodin's philosophy, especially the "field theory," see my article on him in *The Dictionary of Modern American Philosophers*, ed. John R. Shook, 4 vols. (Bristol, UK: Thoemmes Continuum, 2005), vol. 1, pp. 283–288.

[4] Josiah Royce, *The World and the Individual*, First Series (New York: Macmillan, 1899).

independent); *mysticism* (independence is mere appearance, belying a deeper immediate unity of all that is); *critical rationalism* (to say that something *is* means to have an objectively valid idea of it); and Royce's own view that *to be is to be uniquely related to a totality or a whole*. In this adeptly dialectical survey, Royce reduces each of the first three conceptions to absurdity and contradiction, and their susceptibility to such reduction is the main justification for embracing the Fourth Conception. Without necessarily accepting Royce's criticisms of realism, mysticism and critical rationalism, Boodin embraces the Fourth Conception and actually employs it to restore to realism, mysticism and critical rationalism a share of the truth by placing them in perspective and context. Hence, Boodin's metaphysics is constructive where Royce's is more critical.

To realists Boodin concedes that discreteness is a genuine feature of the universe, especially the discreteness of individual selves, but he defines the relation not as pure independence, but as "reference to an object existing beyond the apperceptive unity of momentary individual consciousness." (TR 251) Here we see how the Fourth Conception of Being may be brought to bear on the reality of discrete individuals, and Boodin is an ardent advocate of realism in this sense. This is a kind of metaphysical (in the Kantian sense of "scientific metaphysics") contextualism. To the mystics (the view he favors the least) Boodin concedes that from each and every perspective there is a felt sense of the encompassing whole, but he will not grant to this felt sense any truth claim, only a feeling claim.[5] To the critical rationalists Boodin grants that wherever there is a truth about things, it is a species of meanings, and as meanings truth and validity have real existence. Indeed, "the meaning which moulds itself on the constitution of reality; which leads to the intended consequences, is precisely the *valid* meaning." (TR 202) But against the critical rationalists Boodin will not allow that any given instance of such real validity is final, permanent or a priori. Hence, determinate judgments of the understanding, in the Kantian sense of those terms, are objective only in their aim to *refer* to objects of actual or possible experience. These judgments are, however, revisable in light of the way that experience grows and changes, as it reconstitutes its objects and judgments in each new durational span. In placing meaning above truth in this way, Boodin anticipates Dewey, the phenomenological movement, and the existentialists. Boodin, then, grants more of a share of the truth about being to the first three conceptions than Royce had, and Boodin is less concerned with criticizing them and more eager

[5] See Boodin, *God: A Cosmic Philosophy of Religion* (New York: Macmillan, 1934), p. 195. Boodin has little praise for mysticism and much criticism in his corpus, but he grants it an important role, albeit grudgingly, in the immediate relation to the real. Hocking, of course, built his synthesis of James and Royce upon the rehabilitation of mysticism, so one need not wonder what that may look like. Simply consult Hocking's major works.

to draw from them for his use their portion of the truth. Although Royce, after reducing each of the first three conceptions to absurdity, a priori, often later invoked genuine insights from them and employed versions of them from the point of view of the Fourth Conception, one wonders how such invocation is appropriate after Royce's critique has been so ruthless and total.

For Boodin as for Royce, then, "to be is to be uniquely related to a whole." Boodin calls his version of the Fourth Conception of Being "pragmatic energism." The notion of "energy" was already quite important for Boodin as early as 1907, two years after Einstein had demonstrated its relation to mass and the speed of light, but it is important to point out that James had made a theme of this idea before Einstein, especially in *The Varieties of Religious Experience* (1902).[6] In *Truth and Reality* Boodin identifies three types of energy – mechanical (involving mass), electrical (including light and magnetism and any other area where mass is not the source of the changes observed – we would today add quantum electrodynamics, for example[7]), and "conative energies or the differences that our minds can make to each other and to things." (TR 303) While Boodin is unwilling to reduce these three types of energy to two or one, since empirical warrant was and is lacking, pragmatically speaking, he nevertheless offers a practical version of the Fourth Conception of Being in defining "relation to" as "making a (predictable) difference to," and this means to possess energy. That is, nothing is real which makes no difference to other things, and energy simply is "ability to make a predictable difference." (TR 303) This sense of the word energy "serves as a convenient name, however thin, for the whole world of process." (TR 303) Here we find epitomized both Boodin's speculative and his pragmatic leanings. He has sufficient pragmatic sagacity to suggest that "energies" are energies because they always make a difference, and then he has the intellectual audacity to make an end-run around the mind-body problem by pointing out that mental energies make a difference in the world as surely as do mechanical and electrical energies. Whether mental energies, electrical energies, and mechanical energies are all energies in just the same sense Boodin will not say – because he has no decisive evidence. Yet, he is willing

[6] See Boodin, "The Ultimate Attributes of Reality," *Journal of Philosophy* 4 (1907): 281–289. Here Boodin lays out briefly his "energism" and explains why the word "predictable" is used in his definition of energy. For a more detailed account see his essays "Energy and Reality, Parts I and II," in *Journal of Philosophy* 5 (1908): 365–375, 393–406.

[7] Indeed this is a safe insertion on our part, since Boodin lived just long enough to offer a brief treatment of a paper on this topic by John Archibald Wheeler and Richard Feynman when the latter were both young upstarts. See Boodin, *Posthumous Papers* (Los Angeles: University of California Press, 1957), pp. 97–100.

upon this basis to adopt the term "energy" as a "convenient name" for the "whole world of process," and to name his view "energism."

It must be clear that Boodin believes he is gaining something by invoking this term "energy" – something more than he could achieve had he simply defined reality as "to be is to make a (predictable) difference." This latter formulation seems to reduce all metaphysics to a pragmatic epistemology, which might sit well with James in his anti-abstractionist mood or Dewey in his instrumentalist mood, but hasn't sufficient attraction for Boodin (as indeed it did not for James or Dewey in other moods). The assertion of the idea that *energy* is what really *is* gives Boodin a toehold in physics and in psychology, in metaphysics and in epistemology, without committing him to the primacy of either side in these pairs. Hence, between the horns of the idealistic and radical-empiricist versions of pragmatism. To use Boodin's term, energy provides him with some "stuff" to talk about, and metaphysics is about "stuff."

What might be said about the cosmic "stuff" called "energy"? Among other things, it exists in fields that possess genuine forms.[8] But these forms are varied, contingent, dynamic, active, asymmetrically temporal, and creative. Boodin had begun his writing career by criticizing Royce's eternalism and advancing his own conception of time. And the only other reality apart from energy for Boodin is time. Time is not energy but "creeping, dynamic non-being." Time and energy have dynamism in common, but while energy is a constructive maker of differences, time is a limiter of differences that can be made. Time is not sequentiality or seriality for Boodin (and here he follows Royce's critique of Kant), but an intrinsic mode of limitation in energistic processes (and here the idea is entirely his own). As we know, not just *anything* can happen in the universe, but in energy (as defined) we could identify no particular reason for this. The reason change occurs intelligibly in energies as they modify one another is because time limits it. Yet, no change would be intelligible for Boodin unless there were a *direction* to the change. There need not be an ultimate or fore-ordained end of all change, but time limiting energies in their processes of mutual modification does not a universe make. These energies must be *achieving* something, and indeed, mind itself is one of the "directions" that the universal process has achieved. We see here echoes of Peirce's notion of the "law of mind," and indeed, Boodin was in Cambridge when Peirce gave his 1898 lectures on logic that were so

[8] The "field" concept is most thoroughly discussed by Boodin in *God: A Cosmic Philosophy of Religion* (New York: Macmillan, 1934). See also Boodin, *Cosmic Evolution* (New York: Macmillan, 1925), p. 192; and *The Social Mind* (New York: Macmillan, 1939), pp. 158–159, 161 n.32; and *Posthumous Papers*, pp. 10–11, 84, 88, 97. James was working with the idea of "fields" in the metaphysical sense when Boodin was a student, but never came to any satisfactory conclusions about the idea.

epoch-making for Royce. The point is that it is no accident that the mind, when it knows, knows by detecting both the pattern and direction in differences in its own experience. The mode of limitation (time) and the mode of construction (energy) are already present. Mind is both the outcome of a past process and a part of the on-going process of energies, as limited temporally, engaged in mutual modification. One cannot think everything at once, and time prevents these energies from collapsing all into a single nexus of disorganized energies. Mind is already itself a *direction* energies have taken, and it is unsurprisingly attuned to other processes which follow similar directions. Boodin does not think the entire universe has to be known by minds, or even be intelligible to minds (and here he departs markedly from Royce), but he does know that mind will not detect any change that has no direction. Thus, *value* in the form of directional, temporally limited change is immanent in all meaning, and hence in all truth judgments.

Truth. While far more could be said about reality according to Boodin, we are now in a position to say something of his view of truth. We have already noted that meaning is more fundamental than truth for Boodin, and that truth is one kind of meaning. This marks him as a pragmatist in an important way, as I mentioned earlier in the discussion of Royce. Truth has its roots, for Boodin, in "certain instinctive demands of our nature." (247) We are beings whose existence and development has had a *direction*, historically, and the directionality of our past development lives on in our present instincts. These directions, raised to the level of reflection, present us with ideals – future purposes to be achieved in experience, immanent now in the way that limiting time and constructive energies permit. Boodin aims in this connection to present an epistemology he calls "pragmatic realism," and is thus obliged to say what he means by both terms.

Regarding the "pragmatic" side of his epistemology, Boodin is attracted by the way that pragmatists emphasize function in truth, and see it as a means of regulating conduct in concrete experience. In this connection, Boodin offers a set of functional postulates that enable us to set off truth from non-truth in reflecting upon and returning to experience. These postulates are "presuppositions" that are "implied in all knowing." (TR 126) These are the "laws" of consistency (logical requirements of thought), totality (systematic connection of thought), duality (subject-object relation in all consciousness), and finitude (that all thought must be finite). A more admirable combination of Roycean and Jamesian theories of truth would be difficult to imagine. These laws show in a general way how truth claims all share certain functional presuppositions in the absence of which no evaluation of a truth claim can be achieved in experience. An allegedly infinite thought, or a thought with no thinker or no object, or a self-contradictory thought, or a thought with no systematic relation to a larger whole of experience can make no *predictable* difference in experience. Hence, the thought fails to have the energy which

thought *is*. It cannot be true. But in noticing this pragmatic feature of truth we have not solved the problem of truth in the least. The fact that truth functions in experience points us *towards* the deeper epistemological issues rather than solving them. And here Boodin makes no secret of his impatience with pragmatists who may take their functional account of truth and try to slip away from the conversation before someone asks "why?" As Boodin states "But is truth not reality? the hard-headed critic always comes back." (TR 189)

The deeper problem that a pragmatic conception of truth points us towards is that while we rarely if ever aim at the whole of reality in stating a truth, nevertheless truth is something that "is always teleological, because it exists for the sake of a relation to a larger whole." It is not enough simply to recognize that all our thoughts presuppose connection to our other thoughts. We must also recognize that *truth exists*, and in so doing bears a relation that *is* a direction towards the whole of reality. What Boodin is articulating here is an idea very close to the more celebrated distinction later made by Dewey between (mere) warranted assertibility and Peirce's conception of "truth" as the opinion fated to be ultimately agreed to by all who investigate, while "the object of that opinion is the real."[9] It is the recognition that truth must, beyond its functionality, point us towards what is *real* that grounds Boodin's *realism*.

Here we arrive, therefore, at a sense of the second of the two terms with which Boodin names his epistemology, "pragmatic realism." To be a realist in epistemology does not mean we must embrace unconditionally the mind-independent existence of objects subsequently known. Rather, we must accept that in knowing anything we know more than our minds. What we know is the meaning and direction of a particular and unique standpoint upon the real, a perspective. And this restates epistemologically the Fourth Conception of Being, as I earlier indicated. Objects might exist without ever being thought, but they could have no significance or meaning if they did – i.e., nothing would be "true" of them. To make objects depend upon thought for their *existence* is the mistake idealists, such as Royce, make according to Boodin. But there is an important gap between saying nothing could be *true* of unthought objects, and saying unthought objects cannot *exist*. The former view is consistent with realism, for Boodin, while the latter is not. One cannot know the latter claim is true, and in making it one reduces the object of thought surreptitiously to one of its functional presuppositions (the law of totality) and eliminates its intrinsic reference to any reality, including the reality of its own existence. Hence, Boodin's realism is actually implied by his

[9] John Dewey, *Logic: The Theory of Inquiry*, vol. 12 of *The Later Works*, ed. Jo Ann Boydston (Carbondale: Southern Illinois University Press, 1986 [1938]), p. 343n.

fallibilism – thought is limited metaphysically by the way time, energy and direction are manifest in thought, and in terms of the content of thought by the way the object of thought presupposes certain pragmatic or functional laws, while it simultaneously bears a concrete and positive relation to other (mental and non-mental) energies to which it necessarily refers. This is the context of thought, its finite intent in relation to its temporal existence.

Conclusion

Boodin's theory is far more nuanced than this brief summary can show, and far more impressive. Yet, it is hoped that this short account might encourage the reader to explore not only this book, but also Boodin's subsequent books in which the details of this general philosophical position are worked out in exquisite detail. Boodin sacrifices neither artful prose, nor empirical detail, nor systematic organization and logical acumen in offering his worldview. This is a rare achievement in philosophy. He stands between the idealistic pragmatists and the radical-empirical pragmatists in a way that still has not been surpassed, offering a path to the rehabilitation of much of what needs to be saved from idealistic pragmatism without in the least giving in to its a priorism.

Writings by Josiah Royce

THE ETERNAL AND THE PRACTICAL

Josiah Royce. "The Eternal and the Practical." *Philosophical Review* 13.2 (March 1904): 113–142.

Read as the Presidential Address at the third annual meeting of the American Philosophical Association, at Princeton, December 30, 1903.

There are two general tendencies of opinion which nearly all recent thinkers, whatever be their school, seem disposed to favor. The first of these tendencies is that towards a considerable, although, in different thinkers, a very varying, degree of empiricism. "Radical empiricism," such as that of Professor James, has its defenders in our days. A modified, but still pronounced, empiricism is found in more or less close and organic connection with the teachings of recent idealists, and of various other types of constructive metaphysicians. The second of the contemporary tendencies to which I refer is closely associated with these modern forms of empiricism. It is the tendency towards what has been lately named 'pragmatism', the tendency, namely, to characterize and to estimate the processes of thought in terms of practical categories, and to criticise knowledge in the light of its bearings upon conduct.

I am speaking, so far, not of precisely definable theses, but expressly of tendencies. Whatever may be the rationalistic bias or tradition of any of us, we are all more or less empiricists, and we are so to a degree which was never characteristic of the pre-Kantian rationalists. Whatever may be our interest in theory or in the Absolute, we are all accustomed to lay stress upon practical considerations as having a fundamental, even if not the most fundamental, importance for philosophy; and so in a general, and, as I admit, in a very large and loose sense of the term, we are all alike more or less pragmatists. These, then, are common modern tendencies, which thinkers of the most various schools share. In view of these facts, we have a right to rejoice in the degree to which we have come, despite all our differences, to a certain unity of spirit. On the other hand, even in recognizing this attainment of a certain degree of unity, we have also defined the central problems of modern investigation. They are, first, the problem as to the place which our acknowledged and indispensable empiristic tendencies ought to occupy in the whole context of our philosophical opinions; and, secondly, the problem as to the share which our practical postulates, our ethical undertakings, our doctrine of conduct, ought to have in determining our entire view of the universe.

I

Empiricism, its worth, its justification, its limitations, its lesson – these together form an old story in controversy. I propose in this address, which the kindness of the Association has called me to prepare, to ask your attention to the other of the two tendencies which I have mentioned. I shall try to discuss some of the general relations between our ideals of conduct and our acknowledgement of truth. I need not pause to set forth, in any detail, the well-known fact that the question thus indicated is in its general form by no means a modern question. Both Stoics and Epicureans made it prominent. Earlier still, in consequence of the methods of Socrates, both Plato and Aristotle gave it a significant place in their theories of truth. In modern thought, again, as I also need not at length describe, this problem is by no means confined to contemporary philosophy. Kant's contrast between the theoretical and the practical reason gave our question central importance for the structure of his own system of doctrine. Fichte's philosophy is a deliberate synthesis of pragmatism with absolutism. Hegel made the question a fundamental one in various places in his Logic. In the *Phänomenologie*, the romantic biography of the *Weltgeist*, as Hegel there narrates, the tale has all the principal crises due to the conflicts of the theoretical with the practical reason, while all the triumphs of the hero of this story consist in reconciliations of pragmatic with theoretical interests. Thus, then, the main problem of pragmatism is no more exclusively modern than is that of theism or of empiricism. The occasional efforts to represent the newer insights upon this topic as wholly due to the influence of the most recent doctrines of evolution, and as wholly replacing certain 'preëvolutionary' tendencies of thought, – these efforts, I say, where they exist, result from fondness for over-emphasizing the adjective 'new', – a fondness from which we all in this day suffer, whether we are philosophers or business men, promotors or investors, trustees of universities or humble investigators. There is, indeed, in a sense, a new pragmatism; for the thought of to-day has its own inspirations, and, like any individual tendency in the spiritual world, it is no mere echo of other tendencies or ages. But pragmatism is ancient, is human, has been faced countless times before and will be considered countless times again, so long as men labor for the good, and long for the true. We are here dealing with pervasive tendencies of modern opinion indeed, but not with startling new discoveries, – with questions of to-day, but with ancient issues also, – with problems which modern democracy may emphasize, but which old religions and social orders already made familiar to the wise men of yore.

For this very reason, however, now that I attempt to discuss some aspects of our problem in the light of contemporary interests, it seems to me advisable not to limit my discussion by attempting to keep within the bounds of a direct polemic against such recent expressions of opinion upon the subject as I do not altogether accept. There are several very notable volumes that have been,

of late years, devoted to making explicit certain forms of pragmatism. Professor James's inspiring *Will to Believe*, the recent Chicago *Studies in Logical Theory*, by the members of Professor Dewey's vigorous and productive school, Mr. F. C. S. Schiller's essays published under the title *Humanism*, – these are books of the day, all well known very probably, to every one of you. It would be a tempting task to try to review some one or perhaps all of them. But, as I have said, while the books and the persons are indeed new and unique, the issues are old. I am deeply interested in the persons; but I have time in this paper only for some few of the main issues. While I shall freely refer in general to the current literature of pragmatism, my main argument is one that would remain valid even if the issues of pragmatism were to come to our notice as ancient questions, and not as incidents of the literature of our times. While, then, I shall indeed refer now and then to this literature, I shall not try to treat it in any explicit way. Polemic, whenever it refers to any one author, must rest upon exposition; exposition requires more time than this occasion allows me, raises questions of an exegetical character, and usually dissatisfies the author whom you expound, unless in the end you agree with him in opinion. As Wundt once remarked during a literary controversy: "We are all most erudite with respect to our own books" ("Sind wir doch alle in unseren eigenen Büchern am besten bewandert"). I constantly try to become more or less erudite regarding the contents of other men's books; but this is no place to trouble you with an attempt to display such erudition, or to force my colleagues to point out how ill I may have succeeded in understanding them.

I propose, then, to try to state the relation of the doctrine of conduct to the theory of truth as if the question were not especially characteristic of to-day. I propose to treat it rather as a question of what I shall call eternal importance. This question is: How far is our knowledge identical with an expression of our practical needs?

Nevertheless, I may still permit myself to make one merely personal confession before I go on to my main task, – a confession which relates, indeed, to a totally ephemeral matter. Being, as I just said, more erudite than are the rest of you regarding my own writings, I may venture to tell you that once in my life, before I fell a prey to that bondage of absolutism wherein now I languish, there was a time when I was not a constructive idealist of any sort, and when, if I understand the meaning of the central contention of pragmatism, I was meanwhile a very pure pragmatist. Accordingly, I published in the year 1881, in connection with the Kant centennial celebration of that year, an essay entitled: "Kant's Relation to Modern Philosophical Progress." I was then twenty-six years old and had been deeply influenced by Professor James's earlier lectures and essays. My paper was printed in Dr. Harris's *Journal of Speculative Philosophy*. Nobody amongst you is likely to have remembered, even if he has ever read, that paper. It was a mere sketch.

But since it expressed a sincere effort to state the theory of truth wholly in terms of an interpretation of our judgments as present acknowledgments, since it made these judgments the embodiments of conscious attitudes that I then conceived to be essentially ethical, and to be capable of no restatement in terms of any absolute warrant whatever, I may assert that, for a time at least, I did seriously struggle not only to be what is now called a pragmatist, but also to escape falling into the clutches of any Absolute. When later, however, I fell, and came to believe, as I now steadfastly do, that it is one function of the truth to be, amongst other things, actually true, I do not think that I ceased to be, in a very genuine sense, still a pragmatist, although no longer possessed, perhaps, of what Hegel would have called the pure agility which I then used most earnestly to cultivate. I still am of the opinion that judging is an activity guided by essentially ethical motives. I still hold that, for any truth-seeker, the object of his belief is also the object of his will to believe. I still contend that the truth cannot possibly be conceived as a merely external object, which we passively accept, and by which we are merely moulded. I still maintain that every intelligent soul, however confused or weak, recognizes no truth except the truth to whose making and to whose constitution it even now contributes, – no truth except that which genuinely embodies its own present purpose. I earnestly insist that knowledge is action, although knowledge is also never *mere* action. I fully accept the position that the judgment which I now make is a present reaction to a present empirically given situation, a reaction expressing my need to get control over the situation, whatever else my judgment may also express. I fully accept the position that the world of truth is not now a finished world and is now in the act of making. All this I accept, even although I may nevertheless appear to be bound, by reason of my other convictions, fast in the chains of absolutism. All this I daily teach, even while, as a fact, my only final hope, as a seeker of truth and as a human being, is in the eternal.

At all events, however, now that I can say all this, perhaps it will not seem to you as if, when I undertake to discuss the relations of the principles of conduct to the theory of truth, I shall be doing so without any comprehension of the meaning and the human interest of pragmatism. As I said at the outset, we are totally, all of us, more or less pragmatists. The question is solely one regarding the due place of that side of our doctrine in the whole organism of our convictions.

II

Without expressly expounding or criticising the opinions of anybody else, although of course without attempting to be original, let me first try to state a doctrine that, according to my conception of the matter, emphasizes, as fully as I am able to emphasize, the motives upon which I suppose pragmatism to

rest. Then let me try to explain why I believe that this view of the nature of the knowing process must be, not merely set aside (for within its limits it is, as I conceive, a partial statement of the truth), but supplemented, so that it may be aided to state the whole truth.

To begin, then, the exposition of what I take to be the spirit of pragmatism, – thinking, judging, reasoning, believing, – these are all of them essentially practical activities. One cannot sunder will and intellect. A man thinks about what interests him. He thinks because he feels a need to think. His thinking may or may not be closely linked to those more worldly activities which common sense loves to call practical. But the most remote speculations are, for the man who engages in them, modes of conduct. As contrasted with other men, the thinker, so far as his thoughts do not directly link themselves to the motor processes usually called practical, appears, when viewed from without, to be an inactive person. An anecdote records how a servant woman in Darwin's household ventured to suggest that the old gentleman must be so delicate as he was in health because, as she said, he lacked occupation, and only wandered about looking at his plants, or sat poring over his papers. Whether the anecdote is true or not, the thinker often seems to casual observers to be inhibited, held back from action, hopelessly ineffective. But this appearance we know to be but a seeming. The thinker plans motor processes, and in the end, or even constantly while he thinks, these processes get carried out. The thinker makes diagrams, arranges material objects in classes and in orderly series, constructs apparatus, adjusts with exquisite care his delicate instruments of precision; or he takes notes, builds up formulas, constructs systems of spoken or written words to express his thoughts; and ultimately, in expressing his thoughts, he may direct the conduct of vast numbers of other men, just as Darwin came to do. Meanwhile, even if viewed from within, from his own conscious point of view, the thinker's ideas are not mere objects of contemplation upon which he passively gazes. They are known to him as his own deeds, or at least as his plans of action, whose presence to his mind is determined by a series of acts of attention, – of acts, too, which are inseparably associated with tendencies to use words or other symbols, to arrange external objects in orderly series, to handle his instruments, to control the material objects which concern him, and inwardly to affirm and to deny. And even affirmation and denial have typical outward expressions in conduct. A thought which has no conscious reference to a deed, which involves no plan of conduct, which joins nothing together that was so far divided, which dissects nothing that was so far whole, which involves no play of active attention from object to object, which voluntarily asserts nothing, and which denies nothing, which neither accepts nor rejects, but only passively contemplates, is no thought at all, but is a vacant staring at nothing in particular by nobody who is self-conscious. Thought, indeed, often involves a temporary suppression of outer conduct,

for the sake of considering plans of conduct. But plans of conduct, so far as they are not yet outwardly expressed, are known to our inner consciousness only when possible deeds are begun, but are more or less completely suppressed as soon as they are fairly initiated, – and the passage to the outward expression of thought is not due to the appearance of a new sort of consciousness, which alone is to be called volitional, and which, as volitional, is to be distinguished from every intellectual process. No, the transition from thought to externally significant conduct is rather due to the removal of certain inhibitions. These inhibitions, so long as they persist, keep the thinker from letting those activities which he inwardly rehearses, go free in the form of outwardly manifest words, of arrangements of external objects, and of expressive bodily attitudes such as are those of affirmation and denial.

For the rest, you have only to observe the motor activities of any vivacious disputant or lecturer who freely expresses his thought, to observe how intensely practical are the attitudes in which even decidedly abstract thinking processes inevitably display themselves, so soon as such inhibitions are actually removed. The vivacious disputant or expounder points out imaginary objects with his extended forefinger, and imitates their contour, their movement, their arrangement, their inner structure, by an elaborate display of gestures. His pointings are indices of his subjects; his mimicry portrays his predicates. He affirms by pounding with clenched fist against the palm of his other hand, or upon his desk. Or, again, in case of his more abstract and less contentious assertions, he perhaps gently lays his forefinger across the palm of the opposing hand, or lays it upon the forefinger of this hand, thereby quietly, but impressively, showing you how he has learned to lay his finger upon the very truth itself. He denies by means of gestures of avoidance, of aversion, or of destruction. He harmlessly, yet in a spiritual sense seriously, threatens you, his opponent, with frown, with glittering eye, with shaking fist, with attitudes of defiance, or of crushing intellectual hostility. He invites you, if you are nearer to him in opinion, by winning gestures to come to his embrace. If the controversy is vigorous, then as he affirms or denies, he clenches his jaws and shows his teeth, Or in scorn perhaps at your errors, he makes the well-known but less marked facial gesture that Darwin describes as the act of slightly uncovering the canine tooth on the side towards the enemy. If he becomes very calm, pursuing in his thought extremely abstract and elusive truths, his eye, or his pointing hand, begins to search out small or distant objects. I know a distinguished public lecturer who, whenever his topics grow problematic, follows cautiously with his eyes the lines where the wall and ceiling of the room meet, then perhaps lets them run down the corner of the room, where the two walls meet, and then calmly announces in words the result of his quest. I remember an aged and optimistic philosopher, now dead, whose every expository period was wont to begin with the suggestion of a problem, but to end with its often highly abstract, yet always triumphant

solution. His thoughtful and extremely mobile countenance was a mass of wrinkles, which time and the defense of the truth had worn. As each new sentence set out upon its lengthy course, and as the problem grew intense, this venerable thinker's facial wrinkles used to twist into a marvelous and often terrifying lack of symmetry. One wondered whether those tangled curves could ever again acquire a restful aspect. But as the end of the sentence approached, they always, at the fitting moment, triumphantly passed back again into a beautiful symmetry, and through this blessed relief of tension the evenness of the truth was at the close made quite manifest to everybody present. I do not indeed well remember what this philosopher's opinions were, so busy was I wont to become in watching his countenance. But I gathered that his optimism was a sort of inner comment of his consciousness upon his ceaseless joy in discovering how every muscular strain, whereby his facial wrinkles could possibly be complicated, was certain in the end to pass over into symmetry and quiescence. As he had for many years carefully experimented upon this topic, and as no twist of his wrinkles had ever yet failed to yield to this mode of treatment, he seemed to feel very sure about the universe. The subjects of his assertions might be as contorted as fortune chanced to make them; his predicates were sure to consist of symmetrical curves of relief, and so of peace. Such, you see, was the pragmatism of this venerable sage.

What such seemingly trivial facts illustrate holds true, in principle, of at least one aspect of the inner life of all of us. Our thinking is indeed from moment to moment a consciousness of our adjustment to our present experience. This adjustment is our own act. We perform this act, not capriciously, but because we find therein our conscious relief, our movement in the direction of the fulfillment of our own purpose. Unless I am interested in expressing myself, in actively reading my own purpose into my world, you shall not induce me, by any device, to know or to express any truth whatever about what is not myself.

III

These, then, are considerations which suggest an attempt, not only to define our thoughtful consciousness in essentially practical terms, but also to define the objects about which we think, yes, the very reality of which we are conscious, in similarly pragmatic fashion. For, in the first place, although objects of experience seem, from a well-known realistic point of view, to be given to us whole, with all their properties and relations, as objects independent of our will, and so as objects in their essence extraneous to our consciousness, – still an equally well-known critical method of reflection, when linked with the pragmatism whose basis we have now expounded, tends to destroy this realistic seeming. For what is directly given to us at any

moment (that is, what is immediately and *merely* given to us) is simply the fact of our special momentary need for further insight and for further action. What at any moment we actually see, what we clearly think, what we make out of the given, that is not merely given to us, but is also *ours*, – not ours as our mere caprice, independent of the given need, but ours as what Professor Dewey rightly calls our response to the situation, our furnishing of the needed predicates, our recognition of the object, our adjustment of deed to present want, in brief, as I should say, our expression of ourselves under the conditions.

Hence it is not true that we merely find outer objects as independent of our will, and as nevertheless possessed in all their independence of their various predicates, qualitative, relational, substantial, individual. We find them possessed of characters, only in so far as we ourselves coöperate in the construction, in the definition, in the linkage of these very predicates, which we then ascribe to the objects. Since, to be sure, our need of thus defining our objects is indeed given to us, as this brute fact of our momentary need itself, as the bare datum that we must indeed act in order to succeed, and since, in case we are said to come to an understanding of our objects, we succeed in dealing with our need by virtue of just these special acts of ours, that is, by virtue of making these assertions, of ascribing these predicates, of living out just these beliefs, – since, I say, all this is true, we are accustomed to say that it is the object itself whose nature forces upon us just these predicates. For, in order to relieve our need, we are indeed constrained, in general, to define our object thus and thus. But, as a fact, nothing can force you except your own need. If you have no interest in the object, its supposed independence of your will can impose upon your will no recognition of this its barely external nature. You observe what you need to observe; and in observing you partly fulfill your purpose by diminishing your need; and what you find, as you thoughtfully review your observations, is the expression of your own thoughtful nature in the object, – an expression always conditioned by your need, but also always conditioned by your devices as a thinker, by your categories, by your modes of activity. For instance, does your observed object, as you dwell upon it, come to be possessed for your consciousness of definite numerical complexity? Then that is because you have needed to count, and, counting, have not merely found, but have constructed, both your numerical predicate and the relation of one to one correspondence between the constituents of your predicate and the attentively seized constituents that you now indeed find in your object, but find only in so far as your need has led you, dwelling upon these elements, to divide by your attention what sense furnishes to you only in that problematic confusion which constituted your very need of counting. Thus counting is an expression of your purposes; and sense, when uncounted, shows you no definitely numerical groups; but, at best, furnishes the stimulus and the support of the need to count. This case is typical.

What holds of numerical complexity, holds of every intelligible aspect of experience. What you find, then, as barely given in your experience, are needs that can be thus or thus met, tensions that can be thus or thus relieved by the response of your intelligence, and objects that possess a meaning, only in case you behold in these objects the expression of your own work in meeting your needs. As Kant said, you can get nothing defined and intelligible out of your object except what you have put into it. Yes, as Kant might have said, you get nothing defined and intelligible out of your object except when you merely reflect upon what even now you are putting into it, by active responses to stimuli, that is, to needs, – responses which tell you what your object is only by letting you see what just now you must do about your object. To be sure, since your need at every point accompanies, and so moulds your deed, you never feel free to think this or that of your presented object. For you are bound fast by your own need. The object is therefore yours to construct, but not your to create; and this again is what Kant said. And this is the aspect of the object which realism falsely emphasizes. My need is the controller of my will; though even my need, although given, is not given as an object independent of my will. When realism asserts that, independently of me, my object is possessed of the characters that my intelligence is forced to find in it, the truth of the realistic assertion, as it is usually formulated, seems to lie mainly in the validity of the social judgment that anybody, possessed merely of my needs and of my present resources, would perforce define his world just as I now do mine. This social judgment is human; but it is itself only the expression of one of our deepest needs, namely, the need of companionship, the need to acknowledge the presence of our fellows and to sympathize with their needs. Apart from this social basis of realism, the ordinary realistic interpretation of experience would turn upon the most barren of fancies. The object is never merely given to me, but is given only as the result of a process. It is that which, through my own construction, I find as the momentary expression of my own effort to satisfy my needs. Now sunder that which I thus find from that constructive life whose expression it is. Say that not only before I needed, but before anybody needed, and quite independently of my need, or of any need, there was and is that which my need led me to find as my construction. To say this is realism. And this is what I call a barren fancy, because, when one looks closer, one finds that to say this becomes needless.

Over against such realism, the pragmatism that we are now defining rightly insists, I think, that what you find in experience is what it is found to be, namely, an object in so far as it is characterized through and in your thoughtful deeds.

IV

So far we have, then, the statement of the foundations upon which rests, if I rightly understand the matter, what I shall call pure pragmatism. This pure pragmatism, as we shall soon see, is held unmodified by nobody. Yet there exist those who often speak as if this were their whole doctrine of knowledge. Let us, then, for the moment, take this doctrine as it stands, and try to be for a moment pure pragmatists. If what we have just stated shows the nature of our thought and of its objects, what room is there left for any form of absolutism? This fluent realm of transient meanings, where whatever is merely found, as brute datum, is nothing more than a query, a problem, a need, while whatever is both found and characterized, that is, whatever is experienced as a whole, intelligible, present object, is inevitably an at least partial fulfillment of a present need, – well, to what universal laws of thought or being can such a realm conform? Can such a realm be the expression of any truth that is either eternal, or absolutely authoritative? You have your needs, I mine. We both change our needs. What youth hopes is not what age demands. The morning and the evening bring different needs. Let us be pluralists. If, like my venerable friend, any one of us is in need of such objects as, when conceived, give his facial wrinkles symmetry, and his soul peace, and if, by chance, he can uniformly get what he needs, – well, what he gets is his truth. Who amongst us has any better truth? Who wants anything but a prevailing triumphant state of mind? If thinking gives us such a state, we call our thoughts true. Has the word 'truth' any universal meaning whatever except this? When I say: "This belief of mine is true," what can I mean but: "This belief of mine just now meets my conscious needs"?

As soon as we raise this question, we all indeed begin, even as pure pragmatists, to observe, just a little uncomfortably, one need which we have indeed already mentioned, but which we have not yet explicitly defined. It is the need that I before called the need of companionship, the need not only of thinking for ourselves, but of finding somebody who either will agree with us, or else at least, to our mode of thinking, *ought* to agree with us. This need also is a human, and so far, in our account, is an empirical fact, a brute datum, like our other needs. Perhaps it has no deeper meaning than has any rival need of our wavering wits. But, at all events, it is a need that goes along with his other interests to make the philosopher. For a philosopher, however much he may love to speak with tongues, becomes uncomfortable if he chances to observe that he seems to be edifying only himself and not the brethren. My venerable friend aforesaid obviously desired that we who listened to him should all somehow learn to wrinkle our faces just as he did and just when he did, and should so attain the same blessedness as that which he enjoyed. I notice a human weakness of a similar sort even in the most stubborn pluralists, – even in those who come nearest to being pure pragmatists. I find, namely, that a pluralist, when he criticises me, always wants me

to come into unity with him. And I notice that this weakness also shows itself in a very marked and, as I think, partially justified disposition to expound pragmatism in forms which are not altogether pure. There are those who often speak as if they were pure pragmatists. Yet their doctrine has always another side; and the existence of such additions as are often made to doctrines that at first seem to be pure pragmatism shows, I judge, that there is some difficulty involved in leaving the problem of knowledge just where our previous exposition has so far left it. Something is still lacking to complete our picture of what we call truth. For consider: You shall open some accounts of modern pragmatism which, to judge by some of the expressions used, seem to be attempts at pure pragmatism. Yet, as you read further, you shall learn that philosophers ought to take especially careful account of that greatest of modern discoveries, – the doctrine of evolution. Everything is a product of evolution. Must not thought be such a product? Obviously it must. But now, as you further learn from such expounders of pragmatism, one great merit and recommendation of such pragmatism as I have just tried to illustrate is that it shows how, not only thought, in general, but the special categories of thought, categories such as truth, objectivity, reality, are all products of evolution, and of a process of evolution which is determined by need, by stimulation, by the environment, by the growth of our organisms. What we believe thus appears as a result, like our other reactions, – like fire-making, like engine-building, like money-getting, like art, like the family, or like eating and football playing, – a result brought about by the character of our organisms, by the environment that plays upon us, by the desires that burn within us. Thought and its inner products show you, much as these other incidents of evolution do, reality in the making. The processes of thinking, the acknowledgment of these and these objects as real, of these and these principles as true, the toils of science, the warfare of the creeds, the speculations of the philosophers, – these are all like the cat's pursuit of the mouse, or like the kitten's flight after its tail, simply forms of adjustment to the environment. It is, then, a great recommendation of pragmatism that it comes into line with natural history, that it drops the methods which were common in 'preëvolutionary' ages of thought, and that it conceives truth, being, logic, and all the rest of the objects of philosophical reflection, as, like eating and living, mere incidents of that well-known universal process of evolution. You accept evolution. Well, then, pragmatism is a corollary of evolution. Thus are philosophy and science to be reconciled. Now all these observations about the relations between pragmatism and the doctrine of evolution may have their great value in another context. I am not doubting their intrinsic interest. What I inevitably note is, however, that when a man talks in such terms, he seems to me not to be any longer expounding a pure pragmatism. I do not blame him for this. But I do wonder that he will often speak as if he meant to be a pure pragmatist.

The evidence for pure pragmatism, if there is such evidence, must rest on what you now can observe, as to your present thought and its objects. The evidence for the doctrine of evolution must rest upon beliefs that relate to vast numbers of objects such as are supposed somehow to have existed long before you or I or any human being could have been there to acknowledge their existence. Tell me first that you are a pure pragmatist, and that you accordingly believe whatever you just now find it needful for you to believe; and I can, up to a certain point, understand you. Then add that, having read modern books, or having worked in the field, or in laboratories, you just now find it needful to believe in something called evolution, and accordingly to believe in a world that existed before all human beings existed, to believe also in an object called an organism, in an object called an environment, and in various other such conceived objects, and still I follow you. But tell me that you are a pragmatist *because* pragmatism logically follows from the truth of this doctrine of evolution, and then indeed I fail to see what you mean. For when you say: "The doctrine of evolution is true," I ask you: "In what sense true?" If you reply: "True in the pragmatist's sense, viz., as the object of my present conscious and constructive thought, which conceives evolution as a truth, because just now I need so to conceive it"; – well, then you state your pragmatism first, and define your belief in evolution solely in terms of your pragmatism. How, then, can this belief in evolution, – a belief which is a mere instance of your pragmatism, – lend back any of its borrowed authority to furnish a warrant for your belief in the very doctrine called pragmatism, a belief which you presuppose in expressing your evolutionary creed?

But, on the other hand, if you say: "The doctrine of evolution, as a universally valid result of modern science, is to be accepted, not in the pragmatist's sense at all, but because this doctrine, whether we happen to need to believe it or not, is true"; well – then you have once for all either abandoned, or else have profoundly modified, your pragmatism. You have, perhaps, become a realist, or maybe an absolutist. In any case, your belief in evolution can then furnish no warrant for your pragmatism; because in that case you have denied pragmatism in order to define the sort of truth that you attribute to the doctrine of evolution.

Why, then, does a pragmatist, who often speaks as if he meant to be a pure pragmatist, nevertheless boast of his fidelity to the doctrine of evolution? Because, I answer, despite his occasional speech as if he meant pure pragmatism, he is not a pure pragmatist. For all his pragmatism, he does not quite like to confess that he is an evolutionist *merely* because he just now feels the personal need of being an evolutionist, precisely as other people may feel their need of being Mormons, or of believing in witchcraft, or of squaring the circle in some particular way. And, as a fact, he is not an evolutionist in the sense of such pure pragmatism. He is an evolutionist in the sense of supposing not only that he does just now need to believe in the doctrine of evolution,

but that he *ought* to need so to believe. And he strengthens in himself this sense of the ought by reflecting that he lives in an evolutionary age, and that the experts have settled the question in favor of evolution, and that, by appealing to this well-known presupposition, he can get hearers for his doctrine of pragmatism. For a pragmatist, I repeat, is a companionable person; and, moreover, he rightly thinks that he ought to be so. He is not content to see for himself that his opinions have merely the pragmatic sanction; he wants us to agree with him about this very matter. In fact, he needs that we shall find ourselves needing what he needs.

Two motives that tend to modify pure pragmatism appear even in this brief sketch of its complications. Even a pragmatist who wants to be a pure one has an inevitable conception, not only of what he now needs, as he utters this judgment, but of what he ought to need in order to get a warrant for the judgment. And he also has a conception of the need of finding companions who shall be persuaded to agree with him, or who at least ought to be persuaded. Pure pragmatism would be, after all, a lonesome kind of doctrine. I need, and need just now, to assert myself thus. Hence, I judge thus. Hence this is true for me. How obvious all that is! Yes, but how barren, unless I can add: "My need is the human one; it defines a ruling, a standard need. I *ought* to need just this assertion of just this object in view of this situation. I ought; you ought; humanity ought, to characterize this object thus." Only when I can speak thus do I feel at home. Hence a natural fondness of the pragmatist for using terms that suggest appeal to current popular opinion. Evolution is today not only a result of science; it is a catchword, a name for a celebrated 'merger' of all sorts of securities. If you only join the two words 'social' and 'evolution' in your speech nowadays, everybody at once listens to find out what you have to say. Hence, if you want really to feel at home with even your innermost reflective doctrine, you must characterize it as having an important bearing on the structure of society; and you must show it to be a corollary of the doctrine of evolution. Then only are you quite sure of it!

But, then, in what sense do these perfectly normal and natural tendencies inevitably modify your pure pragmatism? I reply, on one side, they illustrate the pragmatist's main thesis; on the other side, they indeed do modify it. They illustrate it; for this tendency to define pragmatism in terms of evolution is itself the expression of an inner need of the pragmatist who makes the evolutionary appeal. This fondness for companionship, which shows itself in a tendency to confirm pragmatism by a use of popular catch-words, notwithstanding the obvious fact that the only logical basis for pragmatism, apart from purely expository illustrations, must be a purely individual and interior reflective process, whereby we notice what happens when we judge, – this fondness for social confirmation, I say, is again the expression of one of the needs of the pragmatist thinker, who all the while teaches that truth, for him, is merely the result of his need for control over his own experience.

Yet if these tendencies, on the one hand, illustrate pure pragmatism, on the other hand, they, with equal obviousness, modify the form that it assumes in the consciousness of the pragmatist himself. He needs, – but *what* he needs is to recognize that his truth is something *more* than the result and expression of his present need. He judges of his objects as he needs to judge; but one of his needs is to be satisfied that his need ought to be what it is. He expresses himself as he just now is; but he aims to express himself so that his fellow may also be one with himself. Inevitably, therefore, the very need of the moment needs control by another than itself, yet by somewhat that is not alien to itself. It needs control; for so soon as it recognizes that it is logically no better than any other possible will to believe, as for instance, no better than a will to believe in witchcraft, or in fairyland, it recognizes its own emptiness. It needs, therefore, control by some other than itself; for a valid principle that should determine what, under given conditions, is the right and rational need, is not identical with the passing content of any merely momentary need, But when the need of the moment thus needs to be controlled, the control that it seeks is not that of a realistic object, independent of itself, but that of some universal expression of need, – an expression that simply makes conscious what the need of the moment is trying, after all, to be, namely, a rational and binding need. Hence, at the moment of expressing one's pragmatism, one loves to appeal to well recognized objective truths, – to evolution, to common sense, to whatever is likely to seem universally valid.

V

We have thus prepared the way to state wherein our first statement of pragmatism has to be modified, even in order that its own need should be expressed.

"I believe what now, with my conditions, and my needs, my judging activity constructs as the present truth for me": there is one form of the assertion of pure pragmatism. All this, we have said, is obvious and barren. Why barren? Because one of the things that I seek, when I judge, is to express something that shall have some value as a standard. A judgment is not only a construction, but a resolve; not only a response, but a precept; addressed possibly to other men, to myself at other times, to whatever reasonable being there may be who has wit to understand me. It not only says: "I believe"; it says: "This is to be believed." The one who judges wills not only his own state of mind, but other states of mind, which he conceives to be constructed in accordance with the rule laid down in his judgment. Unless he does this, he does not judge; he merely croons, or wrinkles his face, or plays with his mental images. Whoever judges is a pragmatist; but, as we have already seen, he means to require you to believe him. And therein he becomes more than a pragmatist.

And so, in case you first judge, and then as a pure pragmatist observe that your judgment is merely your present reaction to this present conscious situation, the very observation, if it is sufficient to your mind to characterize your whole process of judging, at once takes the whole life out of what was but just now your assurance. That is precisely what I do not want my present judgment to be, namely, this momentary feat of attentive agility. I want it to have authority. Suppose that I assert something, and that thereupon my critical neighbor pityingly says: "Yes, no doubt *you* think so." Why may this retort seem insulting? Because it pretends to reduce my judgment to a mere attitude of my own. Now that is just what I do not want my opinion to be. But suppose that just this retort is the *only* one that I am able upon reflection to make to myself. Well, then indeed I am a pure pragmatist. But hereupon my judgments lose all their deepest interest. They do not meet the principal need that they all the while believed themselves to be meeting. It is as when one wakes from a dream-conversation and finds himself talking alone in the darkness. He was but just now responding to the situation according to his insight. He hereupon observes that both situation and response were merely his own momentary datum and construction. How lonesome is this new insight! Now pragmatists, indeed, do not usually feel lonesome. They are excellent companions and very fond of rational society. We have seen why they do not feel lonesome. It is because, like others, they take their judgments about evolution, society, humanity, the good, and the like, to be possessed of a character that no pure pragmatism could express. Having first believed these judgments in the ordinary way, namely, as having an authority which is not of the moment, they then add to all these insights that of their pragmatism; and their pragmatism now seems to them an interesting addition to the rest of their natural history. And so at moments they can speak as if this were a pure pragmatism. This, however, they never really mean.

"But," you may object, "in answering thus the contention of the pure pragmatist, one only illustrates the more, as has already been admitted, the pure pragmatist's own position. For this need to give our judgments authority, this longing not to be merely expressing ourselves as now we are, but to be laying down a rule for ourselves at other times, and for other selves, what is this but one of our present and conscious needs? Do we get authority by merely willing to have it? Do we legislate for other individuals merely by longing to legislate? What have we, after all, when we judge, but the resolve to speak for others than ourselves? Is the resolve the accomplishment, except precisely in so far as it accomplishes itself in just the present judgment?"

You see the point that we have reached in following our problem. The situation is indeed baffling. If the pure pragmatist speaks to us, and so speaking asserts himself, he speaks as one having authority. He may talk of evolution, or he may otherwise bring his doctrine into line with what he conceives to be natural facts or general human concerns and beliefs. He will

talk of such matters as if he were a realist, or an absolutist. And there is one thing that at the very least he will assert, namely, that his account of the process of judgment, and of the relations of the judgment to its objects, is a sound and true account, which everybody who rightly examines the process of judgment will see for himself to be true. As a teacher, then, the pragmatist is much like any other professor. He has his little horde of maxims; he proclaims the truth; he refutes errors; he asserts that we ought to believe thus or so; and thus lays down the law as vigorously as do other men. But, on the other hand, if the pragmatist, trying for the moment to be a pure pragmatist, reflects upon all this that he has uttered, and upon all this labor that he has done under the sun, then he must observe that in case his own view is as a pure pragmatism correct, he has instructed nobody at any time but himself as to any genuinely common truth; since, at every instant, he has merely been assuming fluent attitudes of his own, attitudes precisely as significant as were my venerable friend's symmetrical wrinkles. For upon each occasion of thought, he has faced an inner situation of his own, and has opposed thereto a certain gesticulation called a predicate, and has therein found a certain triumph of what some would call his reason, while he now might well merely call it his own state of mind.

These, then, are the two aspects of the situation of the pragmatist himself. If the pragmatist has taught us a truth, then he has done something more than assume his needful inner attitudes. But if he has merely adjusted himself to his conscious environment by means of his own inner mental construction, then he has instructed nobody and has refuted nobody; and has said nothing that has any genuine meaning for anybody but himself. Accordingly, even when he has contradicted absolutism, in uttering such a contradiction he has merely assumed an anti-absolutist inner attitude of his own. Hence that attitude has involved no refutation of anybody else. The pure pragmatist, therefore, contradicts nobody but himself when he asserts that other people, say absolutists, are wrong. For none of his assertions can relate to anybody but himself as he happens to be when he makes them. So much, then, for the situation of the pragmatist, just in so far as he tries to be a pure pragmatist. But our situation, as his critics, seems to be for the moment at least decidedly complicated. For we can criticise him only by pointing out to him conscious needs that his account of the judging process somehow does not meet. If these needs are not his own, we have not refuted him. If they are his own, then their presence refutes him only because his doctrine, namely, the doctrine that a true judgment is such by reason of its success in meeting the needs that it attempts to meet, is illustrated by our proposed refutation.

How shall one sum up the meaning of these complications? They are not arbitrary inventions of anybody. They belong to the very essence of the situation of any finite thinker. I know of no way but to accept the conscious situation that we find, as well as to observe with the pragmatist that all this

our finding is inevitably no merely *passive* acceptance. When we *both* act and reflect, both observe and construct, are both pragmatists and theorists, what we make out about the meaning of all this fluent process of knowledge is to be summed up, I think, as follows. Hereby our pragmatism will be, not abandoned, but modified.

VI

I have spoken of the need for companionship in our judgments as itself merely one of our given and human needs. But my illustrations have brought to mind, I hope, what I now venture to state as a general principle. It is this: When we feel the need of appealing to somebody else, or to ourselves at other times, in order even to express our opinion that our judgments have a warrant, this our need for companionship is precisely coincident with our need to regard our judgment as true. When the cat pursues the mouse, she presumably does so because she needs the mouse. But if she consciously asserted: "This is a mouse," she would need another cat, or some other critic of truth, as the being who ought to agree with her as to the truth of this assertion. I react to my environment as this present self. But if my reaction is a judgment, it is not only a bit of pure pragmatism; it is an appeal to a judge of truth whom I conceive either to be judging as one ought to judge, or else to be in the wrong. That I feel the need of such appeal, is itself at any moment, indeed, a mere datum, like any other momentary need of mine. But it is just this need that constitutes me a rational being. Let a pure pragmatist undertake to deny this assertion if he will. In denying he will merely assert that I ought not to make it; and in so denying he will appeal to a sound and rational mode of judgment passed upon consciousness in general. As for his own pure pragmatism, he either judges himself that it is a true account of judging in general, or he is no believer in his own doctrine. But if he is a believer in his own doctrine, then he judges that he characterizes our judging consciousness as another person than his present self ought to characterize it.

In brief, to believe that my judgment is true, is to believe that another point of view than my present point of view, in case this other point of view is what it ought to be, actually confirms my own judgment about this object. This other point of view, however, is a point of view that relates to the same object, or else it could not be conceived as confirming my judgment about this object. Whoever believes seriously in the truth of his judgment, not only explicitly makes this present judgment, but implicitly believes two further things, namely: (1) That there is another conscious point of view than his own, and a point of view from which this same object is viewed; and (2) that this other point of view, without being a mere copy of his own, and without his own being a mere copy of it, is so related to his own point of view that each ought to agree with, to supplement, to enlarge, and to confirm the other. Now

while the need to assert the reality of this other point of view is, indeed, one of the needs of the present judging consciousness, it is utterly vain to say that this need is fully *met* by any fact that the present judging consciousness of a finite being itself now constructs and finds present. For if what I find is for me merely my present opinion about my present object, and if I view this opinion merely as my present construction, then I simply do not view my opinion as true at all. I then view it merely as my state of mind. But if I view my opinion as true, I demand that another than my present self shall accept this opinion. This is the very nature of the truth-asserting consciousness. Such a consciousness lives in the light of another than itself. Yet it conceives this other than itself not as a realistic outer and independent object, but as a constructive self, like itself, yet other than its present self, – its own companion, because its own extension and wider expression. The judging self conceives itself as not fully expressed in this judgment, but as needing its own *alter ego* to aid it in its own expression. Herein the cognitive reactions of finite beings are different from other reactions. They seek, indeed, their own; but they seek it not merely *as* their own. They view themselves as essentially partial functions in a process whose unity is subject to one rule, the *ought* of the truth-seeking activity, whose object is this identical object, but whose variety is the actually required variety of points of view regarding this one object.

If this is of the essence of the judging consciousness, then all that pragmatism asserts is, indeed, as far as it goes, valid; but a pure pragmatist is nevertheless self-refuting. We must be pragmatists, but also more than pragmatists. For if I need what is not my present self, if I need another than the present judging consciousness, in order to make it possible for me to assert the truth of my judgment, then, although my predicates are, as pragmatism asserts, the constructions of the present moment, still the truth of my judgment is not a mere construction of the present moment, but belongs to the unity of the various constructive processes of momentary selves, all of which are various expressions of the purpose which each one of them shares, so that, despite their variety, their selfhood is one.

Yet with this result we cannot pause. Our account is still incomplete. The assertion: "My judgment is true," amounts so far to the judgment: "I have companions, other selves who view the same object from other points of view, – but who, as others, are still so one with myself that despite their variety they still *ought* to agree with me, since my *ought* is theirs, and since we are but various functions in the unity of one knowing process." All this implies the notion of the *ought*, a notion without the consciousness of which my present judgment, as we have seen, becomes even for myself, in case I reflect, a vain crooning, a mere wrinkling of the countenance, an empty pounding of my desk, a helpless shouting at nobody and about nothing. But this ought, what can it mean? A realist would say: "It means that if you judge falsely about the independent object, the independent object will perchance eliminate you as

an unfit variation from the evolutionary process, or will in any case catch you and hold you to facts, squirm though you may." This realistic view, so far as it is sound at all, obviously denies the very independence which it pretends to attribute to the object. Nothing can refute me but an experience that is in unity with my own, and that is a function of the very selfhood which is expressed in me. So realism must be translated into conscious, and so, apparently, into directly pragmatic terms. Plainly the *ought* means that my judging activity has a purpose that goes beyond my present partial expression. In other words, my present judging activity has a place in a process of experience such that if my judgment, despite its present success, still on the whole and in the end fails, this process, of which the judgment itself is a part, contains somewhere conscious contents which will show my partial failure. But since no self whose purposes are foreign to mine, or are in any way such as not to include mine, can possibly observe my failure in judgment, or can be conscious of what I mean and how and where I fail of my own purpose, it follows that to say: "I *ought* to judge thus or thus" is to say: "I myself; in a more fully enlightened expression of myself, am so constituted as to detect whether my judgment wholly fulfills or only partially fulfills my purpose." But to say: "We companions, who judge together the same object, we are all subject to the same ought," is therefore to say: "All our various selves are functions not only one of another, but of one conscious Self that somewhere and somehow pragmatically constructs an expression of itself in the light of which our various partial expressions are judged." Such a self I need just in so far as I need my judgment to be true. Such a self is real if my judgment has either truth or falsity.

But now, regarding any grade or type of socially communing selves that might have reached, from various points of view, such judgments regarding their common objects as rightly expressed so much of their *ought* as had yet come to their own consciousness, the same question that we have now repeatedly asked about our present selves would arise afresh. You do not escape the needs which pragmatism feels by merely multiplying the judges, while leaving them all finite. Is their view of the *ought* the view that they *ought* to hold? Are their conscious ways of judging this object only the expression of their social, but still relative, temporary, passing, unstable point of view? Mere multiplicity of opinions alters not in kind the difficulty that first arose in our path as we studied the single momentary judgment. I appeal to my companions to confirm my judgment in case I believe my judgment to be true. If they disagree, I appeal to our common *ought*, that is, to our consciousness of our one selfhood. But even if my companions all agree with me, and even if we all believe together that we ought to agree, we shall no sooner see this to be our common pragmatic attitude towards our experience than we shall need, in order to maintain that our common judgment is actually true, to face the further question "Is there possibly any other point of view than ours

regarding this object, – and one which renders ours in any sense false? Is there any ought that a still more inclusive view of our common purpose would see to be still higher than our ought?" If there is, then our common judgment is merely our present reaction, which is not true even of its own object. We shall need, I say, need in the pragmatic sense, to seek for the answer to these questions. The penalty of not being able to answer them will simply be that we shall have to call our intellectual constructions, so far as we shall then have reached them, mere attitudes of ours, and not any genuine truths at all. For truth is conformity to an ought. And a true ought is one that from every point of view confirms or refutes. Are such questions in themselves answerable? Does the real world contain anywhere the experiences that do answer them? Is there any final ought of judgment at all? Upon this question depends the whole issue as to whether you and I ever make any true judgments at all, or for that matter, whether we make any false judgments. Truth and falsity are indeed relative to insight, to experience, to life, to action, to the constructions which pragmatism emphasizes. But unless these constructions are what they ought to be they are not true. And unless there is an objective *ought* they are not even false. But if there is a true and a false, then there is a view for which the ought is known, – known not as simply a single, transient, unstable, chance point of view, but as the object of one self-possessed and inclusive insight such that it *remains invariant whatever other points of view you attempt to conceive added to it*. Such an insight would belong to a self that did not fail to include pragmatisms of all kinds, but that simply and consciously *included them all*, in such wise that if you conceived other points of view, other reactions to situations, other judgments added, no change would result in the characterizations of its object which this self could view as fitting, permissible, and so true. For the ought is either a real ought or it is nothing. A judgment has its place in a complete system of truth, or else it is not true.

Now when we declare that our judgments are true, we appeal to such a self to confirm them. Of such an appeal our desire for social support and comradeship is merely a special instance, a fragmentary example. When we doubt whether our judgments are true, we doubt whether such a self does confirm them. When we need to call our judgments true or false, we need to conceive, to define, to address, such a self. If there is such a self, then there is truth. If there is no such self, pragmatism can truly assert nothing, can truly deny nothing, stands in the presence of no genuine reality, and can only continue to be conscious of how it wrinkles its wholly unreal countenance in the echoless void, where its assertions meet no genuine response, have not even any real spectators, and are meaningless both to God and to man, since then neither man nor God exists to fill the void.

But if there is such a self, then for every finite instance of life pragmatism remains a perfectly genuine truth, – genuine as our ceaseless longing for the eternal is genuine, – genuine as love and aspiration are genuine. Everything

expresses itself according to its momentary light. Everything finite passes, changes, evolves, asserts itself and resigns itself, utters rules that are sincerely meant to be authoritative, but gives way to the authority of its own higher expression. Everything is practical; and everything seeks nothing whatever but its own true self, which is the Eternal.

For the Eternal is not that which merely lasts all the time. Only abstractions temporally endure. And they are not the life; they are either only a dead image, or again, they are only an aspect of the life. That alone is eternal which includes all the varying points of view in the unity of a single insight, and which knows that it includes them, because every possible additional point of view would necessarily leave this insight invariant.

The possibility of such an eternal is, of course, the possibility of the existence, in a genuine sense together, as a *toturn simul*, of the contents of an infinite series of practical and evolutionary processes. I have elsewhere set forth at length my grounds for believing both in the possibility and in the actuality of such an eternal existence. It is not my purpose, in this address, however, to expound a metaphysical theory for its own sake. I have desired merely to indicate what we need when we attempt to make true assertions.

I conclude, then, First: That pragmatism is right in asserting that every judgment, whatever else it may prove to be, is the expression of a present activity, determined by a consciousness of need, is responsive to this need, and is such as this need determines, – in brief; is a constructive response to a situation, and is not a mere copying of an externally given object.

Secondly: That nevertheless, in so far as we ourselves observe that our present judgment has *only* this character of being our present and passing response to a given situation, we find that we need the judgment to be more than this. This need is the peculiar need that our judgment should be not only ours but true.

Thirdly: That this need for truth is the need that there should be other points of view, other actual judgments, responsive to the same situation, in other words, to the same object. These other points of view we first conceive as belonging to ourselves at other times, or to other selves, those of our companions. We conceive that all these judgments ought, despite their diversity of points of view, so to agree as to confirm one another, and so to unite in one system of truth as to characterize harmoniously the same object.

Fourthly: That these various points of view (in order thus to harmonize) and this *ought* (in order to hold for all of them) must be conceived as belonging to, and as being included within, a single self, whose partial functions these various selves are, and whose common conscious purpose defines the ought to which each of the various judgments is to conform. Such a self we need to conceive in order to conceive our judgments as true; and we need to conceive it as having the same sort of embodiment in concrete experience that our present judgment now has.

Fifthly: Meanwhile, in so far as we conceive this self as like ourselves transient, passing, variable, – its inclusive constructive judgments become once more like our own, not genuinely true, but only special points of view, which determine no genuine ought, and which are mere states of mind, or stages of its experience. Mere magnitude and multiplicity cannot constitute that aspect of consciousness which makes possible a genuine *ought*.

Accordingly, in the sixth place, in order to conceive our judgments as true, we need to conceive them as partial functions of a self which is so inclusive of all possible points of view regarding our object as to remain invariant in the presence of all conceivable additional points of view, and so conscious of its own finished and invariable purpose as to define an ought that determines the truth or falsity of every possible judgment about this object.

Seventhly, and lastly: If there is such an inclusive and invariant self, it is of course complete at no moment of time. It is inclusive of all temporal processes of evolution that could alter our view or any view of our object. Such a self is invariant and eternal, without thereby ceasing at any and every point of time to be expressed in finite and practical activities, such as appear in our own judgments. If there is such a self, our need to make judgments that can be true or false is satisfied. If there is no such self, no judgment is either true or false. The need for the Eternal is consequently one of the deepest of all our practical needs. Herein lies at once the justification of pragmatism, and the logical impossibility of pure pragmatism. Everything finite and temporal is practical. All that is practical borrows its truth from the Eternal.

LOYALTY, TRUTH, AND REALITY

"Loyalty, Truth, and Reality." *The Philosophy of Loyalty* (New York: Macmillan, 1908), chap. 7, pp. 301–348.

In closing my last lecture I said that what ever trains us in the arts of loyalty enables us to enter into a world of spiritual truth. These words were intended to indicate that the loyal life has another aspect than the one hitherto most emphasized in these lectures. Our foregoing account has been deliberately one-sided. We have been discussing the moral life as if one could define a plan of conduct without implying more about man's place in the real universe than we have yet made explicit in these lectures. Hence our discussion, so far, is open to obvious objections.

For, in talking about the good of loyalty, we have indeed appealed to human experience to show us wherein that good consists. But our very appeal also showed us that loyalty is good for a man precisely because he believes that his cause itself, even apart from his service, is good, and that both his cause and its goodness are realities, founded in facts which far transcend his individual life and his personal experience. Now, one may well doubt whether this belief of a loyal man is, in any individual case, a well-founded belief. And if it is not well founded, one may well question whether the loyal man's good is not, after all, an illusory good, which will vanish from his experience as soon as he becomes enlightened. Since any instance of loyalty is subject to this sceptical inquiry, one may doubt whether even what we have called the supreme cause, that of loyalty to loyalty, is a good cause. For any or all loyalties may be founded in illusion, and then it would be an illusion that the fostering of loyalty amongst men is a finally worthy undertaking.

I

Objections of this sort are best stated by those to whom they actually occur as serious difficulties regarding the discussions contained in the foregoing lectures. A dear friend of mine, without receiving any instigation from me to help me by such an act, has so aptly summed up the objections here in question, that I can best show you precisely where we now stand by reading to you a portion of a letter which he has written to me, after hearing the first portion of my account of the good of loyalty.

"Loyalty to loyalty," writes my friend, "doesn't seem ultimate. Is it not loyalty to all *objects* of true loyalty that is our ultimate duty? The object, not the relation, – the universe and the devotion to it, not the devotion alone, is the object of our ultimate devotion.... Is it not the glory of this goal that lends dignity to all loyal search, – our own or that of others? It is because of this goal that we cheer on all to pursue it.... It is because of what we believe about the end of the various loyalties that we are so glad of all the loyalties which make it possible to attain that end. The port gives value to the courses steering for it.... Except for our knowledge of the value of their destination, and of all life lived in quest of that destination, should we be anxious to urge all seekers along their courses? ... Loyalty is a relation.... Can we be loyal to anything, ultimately, except the universe which is the object of all love and all knowledge?"

So far my friend's statement of his difficulty. As you will see, from these two closing lectures of my course which still remain, I cordially share my friend's objection to the definition of loyalty so far insisted upon in these lectures. Our definition of loyalty, and of its relation to the ultimate good which the loyal are seeking, has so far been inadequate. But, as I told you in the opening lecture, we deliberately began with an inadequate definition of the nature of loyalty. We were obliged to do so. I expressly said this in my opening statement. Why we were obliged to do so, and why, thus far in these lectures, we have confined ourselves to developing and to illustrating the consequences of this imperfect definition of loyalty, our closing lectures will of themselves, I hope, make clear. A similar difficulty can be urged against any mere moralism, that is, against any purely ethical theory of the moral life. One wants a doctrine of the real world, or a religion, to help out one's ethics. For, as I have replied to my friend, morality, viewed by itself, has a character that can well be suggested by the parable of the talents. The moral life, regarded simply as the moral life, is the service of a master who seems, to those who serve him, to have gone away into a far country. His servants have faith in him, but the service of his cause always has, for the moral, a certain mystery about it. They can indeed become sure, apart from any solution of this mystery, that their own supreme personal good lies in serving their lord. For not otherwise can they find even the relative peace that lies in a service of duty. But those who serve are not thus altogether secured against a pessimism regarding the whole outcome of human endeavor. For if loyalty is indeed our best, may not even this best itself be a failure?

Or, to use further the similitude of the parable of the talents: It may be indeed our supreme good to serve the master who has gone into the far country. Yet we do not merely want to serve him; we want, like Job, to meet him face to face. Suppose that we should discover the master to be indeed unworthy or a phantom or a deceiver, would even this, our best good, the service of his cause, seem permanently valuable? Should we not say, some day:

To serve him was our best chance of life; but after all even that service was vanity.

In any case, our loyalty implies a faith in the master, – an assurance that life, at its best, is indeed worth while. Our philosophy of loyalty must therefore include an attempt to see the master of life himself, and to find out whether in truth he is, what our loyalty implies that he is, a master worth serving.

To sum up: So far we have defined the moral life as loyalty, and have shown why the moral life is for us men the best life. But now we want to know what truth is behind and beneath the moral life. With my friendly correspondent, we want to see the relation of loyalty to the real universe.

II

What must be true about the universe if even loyalty itself is a genuine good, and not a merely inevitable human illusion?

Well, loyalty is a service of causes. A cause, if it really is what our definition requires, links various human lives into the unity of one life. Therefore, if loyalty has any basis in truth, human lives can be linked in some genuine spiritual unity. Is such unity a fact, or is our belief in our causes a mere point of view, a pathetic fallacy? Surely, if any man, however loyal, discovers that his cause is a dream, and that men remain as a fact sundered beings, not really linked by genuine spiritual ties, how can that man remain loyal? Perhaps his supreme good indeed lies in believing that such unities are real. But if this belief turns out to be an illusion, and if a man detects the illusion, can he any longer get the good out of loyalty?

And as for even this personal good that is to be got out of loyalty, we have all along seen that such good comes to a loyal man's mind in a very paradoxical way. A loyal man gets good, but since he gets it by believing that his cause has a real existence outside of his private self, and is of itself a good thing, he gets the fascination of loyalty not as a private delight of his own, but as a fulfilment of himself through self-surrender to an externally existing good, – through a willing abandonment of the seeking of his own delight. And so the loyal man's good is essentially an anticipation of a good that he regards as not his own, but as existent in the cause. The cause, however, is itself no one fellow-man, and no mere collection of fellowmen. It is a family, a country, a church, or is such a rational union of many human minds and wills as we have in mind when we speak of a science or an art. Now, can such causes contain any good which is not simply a collection of separate human experiences of pleasure or of satisfaction? Thus, then, both the reality and the good of a loyal man's cause must be objects of the loyal man's belief in order that he should be able to get the experience of loyalty. And if his loyalty is indeed well founded, there must be unities of spiritual life in the universe such

that no one man ever, by himself, experiences these unities as facts of his own consciousness. And these higher unities of life must possess a degree and a type of goodness, – a genuine value, such that no one man, and no mere collection of men, can ever exhaustively experience this goodness, or become personally possessed of this value.

How paradoxical a world, then, must the real world be, if the faith of the loyal is indeed well founded! A spiritual unity of life, which transcends the individual experience of any man, must be real. For loyalty, as we have seen, is a service of causes that, from the human point of view, appear superpersonal. Loyalty holds these unities to be good. If loyalty is right, the real goodness of these causes is never completely manifested to any one man, or to any mere collection of men. Such goodness, then, if completely experienced at all, must be experienced upon some higher level of consciousness than any one human being ever reaches. If loyalty is right, social causes, social organizations, friendships, families, countries, yes, humanity, as you see, must have the sort of unity of consciousness which individual human persons fragmentarily get, but must have this unity upon a higher level than that of our ordinary human individuality.

Some such view, I say, must be held if we are to regard loyalty as in the end anything more than a convenient illusion. Loyalty has its metaphysical aspect. It is an effort to conceive human life in an essentially superhuman way, to view our social organizations as actual personal unities of consciousness, unities wherein there exists an actual experience of that good which, in our loyalty, we only partially apprehend. If the loyalty of the lovers is indeed well founded in fact, then they, as separate individuals, do not constitute the whole truth. Their spiritual union also has a personal, a conscious existence, upon a higher than human level. An analogous unity of consciousness, an unity superhuman in grade, but intimately bound up with, and inclusive of, our apparently separate personalities, must exist, if loyalty is well founded, wherever a real cause wins the true devotion of ourselves. Grant such an hypothesis, and then loyalty becomes no pathetic serving of a myth. The good which our causes possess, then, also becomes a concrete fact for an experience of a higher than human level. That union of self-sacrifice with self-assertion which loyalty expresses becomes a consciousness of our genuine relations to a higher social unity of consciousness in which we all have our being. For from this point of view we are, and we have our worth, by virtue of our relation to a consciousness of a type superior to the human type. And meanwhile the good of our loyalty is itself a perfectly concrete good, a good which is present to that higher experience, wherein our cause is viewed in its truth, as a genuine unity of life. And because of this fact we can straightforwardly say: We are loyal not for the sake of the good that we privately get out of loyalty, but for the sake of the good that the cause – this higher unity of experience – gets out of this loyalty. Yet our loyalty gives us what is, after all, our

supreme good, for it defines our true position in the world of that social will wherein we live and move and have our being.

I doubt not that such a view of human life, – such an assertion that the social will is a concrete entity, just as real as we are, and of still a higher grade of reality than ourselves, – will seem to many of you mythical enough. Yet thus to view the unity of human life is, after all, a common tendency of the loyal. That fact I have illustrated in every lecture of this course. That such a view need not be mythical, that truth and reality can be conceived only in such terms as these, that our philosophy of loyalty is a rational part of a philosophy which must view the whole world as one unity of consciousness, wherein countless lesser unities are synthesized, – this is a general philosophical thesis which I must next briefly expound to you.

III

My exposition, as you see, must be, in any case, an attempt to show that the inevitable faith of the loyal – their faith in their causes, and in the real goodness of their causes – has truth, and since I must thus, in any case, discourse of truth, I propose briefly to show you that whoever talks of any sort of truth whatever, be that truth moral or scientific, the truth of common sense or the truth of a philosophy, inevitably implies, in all his assertions about truth, that the world of truth of which he speaks is a world possessing a rational and spiritual unity, is a conscious world of experience, whose type of consciousness is higher in its level than is the type of our human minds, but whose life is such that our life belongs as part to this living whole. This world of truth is the one that you must define, so I insist, if you are to regard any proposition whatever as true, and are then to tell, in a reasonable way, what you mean by the truth of that proposition.

The world of truth is therefore essentially a world such as that in whose reality the loyal believe when they believe their cause to be real. Moreover, this truth world has a goodness about it, essentially like that which the loyal attribute to their causes. Truth seeking and loyalty are therefore essentially the same process of life merely viewed in two different aspects. Whoever is loyal serves what he takes to be a truth, namely, his cause. On the other hand, whoever seeks truth for its own sake fails of his business if he seeks it merely as a barren abstraction, that has no life in it. If a truth seeker knows his business, he is, then, in the sense of our definition, serving a cause which unifies our human life upon some higher level of spiritual being than the present human level. He is therefore essentially loyal. Truth seeking is a moral activity; and on the other hand, morality is wholly inadequate unless the light of eternal truth shines upon it.

This, I say, will be my thesis. Some of you will call it very mystical, or at least a very fantastic thesis. It is not so. It ought to be viewed as a matter of

plain sense. It is, I admit, a thesis which many of the most distinguished amongst my colleagues, who are philosophers, nowadays view sometimes with amusement, and sometimes with a notable impatience. This way of regarding the world of truth, which I have just defined as mine, is especially and most vivaciously attacked by my good friends, the pragmatists, – a group of philosophers who have of late been disposed to take truth under their especial protection, as if she were in danger from the tendency of some people who take her too seriously.

When I mention pragmatism, I inevitably bring to your minds the name of one whom we all honor, – the philosopher who last year so persuasively stated, before the audience of this Institute, the pragmatist theory of philosophical method, and of the nature of truth. It is impossible for me to do any justice, within my limits, to the exposition which Professor James gave of his own theory of truth. Yet since the antithesis between his views and those which I have now to indicate to you may be in itself an aid to my own exposition, I beg you to allow me to use, for the moment, some of his assertions about the nature of truth as a means of showing, by contrast, how I find myself obliged to interpret the same problem. The contrast is accompanied, after all, by so much of deeper agreement that I can well hope that my sketch of the current situation in the philosophical controversies about truth may not seem to you merely a dreary report of differences of opinion.

Professor James, in discussing the nature of truth, in his recent book on pragmatism, begins, as some of you will remember, by accepting the classic definition of truth as the agreement of our ideas with reality. Whoever knows or possesses a truth has, then, in his mind, an idea, an opinion, a judgment, or some complex of such states of mind. If his views are true, then these his ideas or opinions are in agreement with something called reality. Thus, for instance, if a loyal man believes his cause, say, his friendship or his club or his nation, to be a reality, and if his belief is true, his loyal opinion is in agreement with the real world. So far, of course, all of you will accept the definition of truth here in question.

Professor James now goes on to point out that, in some cases, our ideas agree with what we call real things by copying those things. So, if, with shut eyes, you think of the clock on the wall, your image of the clock is a copy of its dial. But, as my colleague continues, our power to copy real objects by ideas of our own is obviously a very limited power. You believe that you have at least some true ideas about many objects which are far too complex or too mysterious for you to copy them. Your power to become sure that your ideas do copy the constitution of anything whatever which exists outside of you is also very limited, because, after all, you never get outside of your own experience to see what the real things would be if taken wholly in themselves. Hence, on the whole, one cannot say that the agreement of our ideas with reality which constitutes their truth is essentially such as to demand that our

ideas should be copies. For we believe that we have true ideas even when we do not believe them to be copies.

Moreover (and herewith we approach a consideration which is, for my colleague's theory of truth very essential), not only does truth not consist merely in copying facts; but also truth cannot be defined in terms of any other static or fixed relation between ideas and facts. The only way to conceive that agreement between ideas and facts which constitutes truth is to think of the "practical consequences" which follow from possessing true ideas. "True ideas," in Professor James's words, "lead us, namely, through the acts and other ideas which they instigate, into or up to or towards other parts of experience with which we feel all the while that the original ideas remain in agreement. The connections and transitions come to us, from point to point, as being progressive, harmonious, satisfactory. This function of agreeable leading is what we mean by an idea's verification." So far my colleague's words. He goes on, in his account, to mention many illustrations of the way in which the truth of ideas is tested, both in the world of common sense, and in the world of science, by the usefulness, by the success, which attaches to the following out of true ideas to their actual empirical consequences. The wanderer lost in the woods gets true ideas about his whereabouts whenever he hits upon experiences and ideas which set him following the path which actually leads him home. In science, hypotheses are tested as to their truth, by considering what experiences they lead us to anticipate, and by then seeing whether these anticipations can be fulfilled in a satisfactory way. "True," says Professor James, "is the name for whatever idea starts the verification process." For instance, then, the verifiable scientific hypothesis, if once tested by the success of its results in experience, is in so far declared true. And similarly, the idea of following a given path in the woods in order to get home is declared true, if you follow the path and get home.

In consequence, every true idea is such in so far as it is useful in enabling you to anticipate the sort of experience that you want; and every idea that is useful as a guide of life is in so far true. The personal tests of usefulness, as of truth, are for every one of us personal and empirical. My own direct tests of truth are of course thus limited to my own experience. I find my own ideas true just in so far as I find them guiding me to the experience that I want to get. But of course, as my colleague constantly insists, we give credit, as social beings, to one another's verifications. Hence I regard as true many ideas that I personally have not followed out to any adequately experienced consequences. The "overwhelmingly large" number of the ideas by which we live, "we let pass for true with out attempting to verify." We do this, says Professor James, "because it *works* to do so, everything we know conspiring with the belief, and nothing interfering." That is, we regard as true those ideas which we personally find it convenient, successful, expedient to treat as verifiable, even though we never verify them. The warrant of these unverifiable truths

is, however, once more, the empirical usefulness of living as if they were verifiable. "Truth lives," says Professor James, "for the most part on a credit system.... But this all points to direct face-to-face verification somewhere, without which the fabric of truth collapses like a financial system with no cash basis whatever. You accept my verification of one thing, I yours of another. We trade on each other's truth. But beliefs verified concretely by *somebody* are the posts of the whole superstructure." The indirectly verifiable ideas, that is, the ideas which somebody else verifies, or even those which nobody yet verifies, but which agree sufficiently with verified ideas, we accept because it is advantageous to accept them. It is the same thing, then, to say that an idea is true because it is useful and to say that it is useful because it is true.

Agreement with reality thus turns out, as my colleague insists, "to be an affair of leading, – leading that is useful because it is into quarters that contain objects that are important." And my colleague's account of truth culminates in these notable expressions: "'The true', to put it very briefly, is only the expedient in the way of our thinking, just as 'the right' is only the expedient in the way of our behaving." "Pragmatism faces forward towards the future." That is, an idea is true by virtue of its expedient outcome. "It pays for our ideas to be validated, verified. Our obligation to seek truth is part of our general obligation to do what pays. The payment true ideas bring are the sole why of our duty to follow them."

The sum and substance of this theory of truth, as you see, is that the truth of an idea is determined by its "success" in yielding what my colleague frequently calls "the cash values in terms of experience," which appear as consequences of holding this idea. These values may either take the form of direct verifications in terms of sensible facts, as when one finds one's way out of the woods and sees one's home; or else the form of practically satisfying and expedient beliefs, which clash with no sensible experience, and which are personally acceptable to those who hold them. It is "expedient" to connect the latter beliefs with sensible cash values when you can. If you cannot turn them into such cash, you are at liberty to hold them, but with the conviction that, after all, the personally expedient is the true.

In any case, as you see, whatever else truth is, it is nothing static. It changes with the expediencies of your experience. And therefore those who conceive the realm of truth as essentially eternal are the objects of my colleague's most charming philosophical fury.

IV

We have, then, an authoritative exposition of pragmatism before us. You must see that this doctrine, whether it be a true doctrine, or whether it be indeed simply for some people an expedient doctrine, is certainly one that concerns our philosophy of loyalty, now that indeed we have reached the place where

the relation between loyalty and truth has become, for us, a critically important relation. May we venture to ask ourselves, then: Is this pragmatism a fair expression of what we mean by truth?

In reply let me at once point out the extent to which I personally agree with my colleague, and accept his theory of truth. I fully agree with him that whenever a man asserts a truth, his assertion is a deed, – a practical attitude, an active acknowledgment of some fact. I fully agree that the effort to verify this acknowledgment by one's own personal experience, and the attempt to find truth in the form of a practical congruity between our assertions and our attained empirical results, is an effort which in our individual lives inevitably accompanies and sustains our every undertaking in the cause of truth seeking. Modern pragmatism is not indeed as original as it seems to suppose itself to be in emphasizing such views. The whole history of modern idealism is full of such assertions. I myself, as a teacher of philosophy, have for years insisted upon viewing truth in this practical way. I must joyously confess to you that I was first taught to view the nature of truth in this way when I was a young student of philosophy; and I was taught this by several great masters of modern thought. These masters were Kant, Fichte, Hegel, and Professor James himself, whose lectures, as I heard them in my youth at the Johns Hopkins University, and whose beautiful conversations and letters in later years, inspired me with an insight that helped me, rather against his own advice, to read my German idealists aright, and to see what is, after all, the eternal truth beneath all this pragmatism. For Professor James's pragmatism, despite its entertaining expressions of horror of the eternal, actually does state one aspect of eternal truth. It is, namely, eternally true that all search for truth is a practical activity, with an ethical purpose, and that a purely theoretical truth, such as should guide no significant active process, is a barren absurdity. This, however, is so far precisely what Fichte spent his life in teaching. Professor James taught me, as a student, much the same lesson; and I equally prize and honor all of my masters for that lesson; and I have been trying to live up to it ever since I first began to study the nature of truth.

So far, then, I am a pragmatist. And I also fully agree that, if we ever get truth, the attainment of truth means a living and practical success in those active undertakings in terms of which we have been trying to assert and to verify our truth. I doubt not that to say, "This is true," is the same as to say: "The ideas by means of which I define this truth are the practically and genuinely successful ideas, the ideas such that, when I follow them, I really fulfil my deepest needs." All this I not only admit; but I earnestly insist that truth is an ethical concept; and I thank from my heart the great pragmatist who so fascinated his audience last year in this place; I thank him that he taught them what, in my youth, he helped to teach me, namely, that winning the truth means winning the success which we need, and for which the whole

practical nature of our common humanity continually groans and travails together in pain until now.

And yet, and yet all this still leaves open one great question. When we seek truth, we indeed seek successful ideas. But what, in Heaven's name, constitutes success? Truth-seeking is indeed a practical endeavor. But what, in the name of all the loyal, is the goal of human endeavor? Truth is a living thing. We want leading and guidance. "Lead, kindly light," – thus we address the truth. We are lost in the woods of time. We want the way, the truth, and the life. For nothing else does all our science and our common sense strive. But what is it to have genuine abundance of life? For what do we live?

V

Here our entire philosophy of loyalty, so far as it has yet been developed, comes to our aid. The loyal, as we have said, are the only human beings who can have any reasonable hope of genuine success. If they do not succeed, then nobody succeeds. And of course the loyal do indeed live with a constant, although not with an exclusive, reference to their own personal experience and to that of other individual men. They feel their present fascination for their cause. It thrills through them. Their loyalty has, even for them, in their individual capacity what Professor James calls a cash value. And of course they like to have their friends share such cash values. Yet I ask you: Are the loyal seeking *only* the mere collection of their private experiences of their personal thrills of fascination? If you hear loyal men say: "We are in this business just for what we as individuals – we and our individual fellows – can get out of it," do you regard that way of speech as an adequate expression of their really loyal spirit? When Arnold von Winkelried rushed on the Austrian spears, did he naturally say: "Look you, my friends, I seek, in experiential terms, the cash value of my devotion; see me draw the cash." My colleague would of course retort that the hero in question, according to the legend, said, as he died: "Make way for liberty." He therefore wanted liberty, as one may insist, to get these cash values. Yes, but liberty was no individual man, and no mere heap of individual men. Liberty was a cause, a certain superhuman unity of the ideal life of a free community. It was indeed expedient that one man should die for the people. But the people also was an *unio mystica* of many in one. For that cause the hero died. And no man has ever yet experienced, in his private and individual life, the whole true cash value of that higher unity. Nor will all the individual Swiss patriots, past, present, or future, viewed as a mere collection of creatures of a day, ever draw the cash in question. If the cause exists, the treasure exists, and is indeed a cash value upon a level higher than that of our passing human life. But loyalty does not live by selling its goods for present cash in the temple of its cause. Such pragmatism

it drives out of the temple. It serves, and worships, and says to the cause: "Be thine the glory."

Loyalty, then, seeks success and from moment to moment indeed thrills with a purely fragmentary and temporary joy in its love of its service. But the joy depends on a belief in a distinctly superhuman type of unity of life. And so you indeed cannot express the value of your loyalty by pointing at the mere heap of the joyous thrills of the various loyal individuals. The loyal serve a real whole of life, an experiential value too rich for any expression in merely momentary terms.

Now, is it not very much so with our love of any kind of truth? Of course, we mortals seek for whatever verification of our truths we can get in the form of present success. But can you express our human definition of truth in terms of any collection of our human experiences of personal expediency?

Well, as to our concept of truth, let us consider a test case by way of helping ourselves to answer this question. Let us suppose that a witness appears, upon some witness-stand, and objects to taking the ordinary oath, because he has conscientious scruples, due to the fact that he is a recent pragmatist, who has a fine new definition of truth, in terms of which alone he can be sworn. Let us suppose him, hereupon, to be granted entire liberty to express his oath in his own way. Let him accordingly say, using, with technical scrupulosity, my colleague's definition of truth: "I promise to tell whatever is expedient and nothing but what is expedient, so help me future experience." I ask you: Do you think that this witness has expressed, with adequacy, that view of the nature of truth that you really wish a witness to have in mind? Of course, if he were a typical pragmatist, you would indeed be delighted to hear his testimony on the witness-stand or anywhere else. But would you accept his formula?

But let me be more precise as to the topic of this witness's possible testimony. I will use for the purpose Kant's famous case. Somebody, now dead, let us suppose, has actually left with the witness a sum of money as a wholly secret deposit to be some time returned. No written record was made of the transaction. No evidence exists that can in future be used to refute the witness if he denies the transaction and keeps the money. The questions to be asked of the witness relate, amongst other things, to whatever it may be that he believes himself to know about the estate of the deceased. I now ask, not what his duty is, but simply what it is that he rationally means to do in case he really intends to tell the truth about that deposit. Does he take merely the "forward-looking" attitude of my colleague's pragmatism? Does he mean merely to predict, as expedient, certain consequences which he expects to result either to himself or to the heirs of the estate? Of course his testimony will have consequences. But is it these which he is trying to predict? Are they his true object? Or does the truth of his statement mean the same as the expediency, either to himself or to the heirs, of any consequences whatever

which may follow from his statement? Does the truth of his statement about the deposit even mean the merely present empirical fact that he now feels a belief in this statement or that he finds it just now congruent with the empirical sequences of his present memories? No, for the witness is not trying merely to tell how he feels. He is trying to tell the truth about the deposit. And the witness's belief is not the truth of his belief. Even his memory is not the truth to which he means to be a witness. And the future consequences of his making a true statement are for the witness irrelevant, since they are for the law and the heirs to determine. Yet one means something perfectly definite by the truth of the testimony of that witness. And that truth is simply inexpressible in such terms as those which my colleague employs. Yet the truth here in question is a simple truth about the witness's own personal past experience.

Now, such a case is only one of countless cases where we are trying to tell the truth about something which we all regard as being, in itself, a matter of genuine and concrete experience, while nevertheless we do not mean, "It is expedient just now for me to think this," nor yet, "I predict such and such consequences for my own personal experience, or for the future experience of some other individual man; and these predicted consequences constitute the truth of my present assertion." I say there are countless such cases where the truth that we mean is empirical indeed, but transcends all such expediencies and personal consequences. The very assertion, "Human experience, taken as a totality of facts, exists," is a momentous example of just such an assertion. We all believe that assertion. If that assertion is not actually true, then our whole frame of natural science, founded as it is on the common experience of many observers, crumbles into dust, our common sense world is nothing, business and society are alike illusions, loyalty to causes is meaningless. Now that assertion, "Human experience, that is, the totality of the experiences of many men, really exists," is an assertion which you and I regard as perfectly true. Yet no individual man ever has verified, or ever will verify, that assertion. For no man, taken as this individual man, experiences the experience of anybody but himself. Yet we all regard that assertion as true.

My colleague, of course, would say, as in fact he has often said, that his assertion is one of the numerous instances of that process of trading on credit which he so freely illustrates. We do not verify this assertion. But we accept it on credit as verifiable. However, the credit simile is a dangerous one here, so long as one conceives that the verification which would pay the cash would be a payment in the form of such human experience as you and I possess. For the assertion, "The experience of many men exists," is an assertion that is essentially unverifiable by any one man. If the "cash value" of the assertion means, then, its verifiability by any man, then the credit in question is one that simply cannot be turned into such cash by any conceivable process, occurring in our individual lives, since the very idea of the real

existence of the experience of many men excludes, by its definition, the direct presence of this experience of various men within the experience of any one of these men. The credit value in question would thus be a *mere* fiat value, so long as the only cash values are those of the experiences of individual men, and the truth of our assertion would mean simply that we find it expedient to treat as verifiable what we know cannot be verified.

Hereupon, of course, we should simply be trading upon currency that has no cash value. Whoever does verify the fact that the experience of many men exists, if such a verifier there be, is a superhuman being, an union of the empirical lives of many men in the complex of a single experience. And if our credit of the assertion that many men exist is convertible into cash at all, that cash is not laid up where the moth and rust of our private human experience doth from moment to moment corrupt the very data that we see; but is laid up in a realm where our experiences, past, present, future, are the object of a conspectus that is not merely temporal and transient. Now all the natural sciences make use of the persuasion that the experiences of various men exist, and that there is a unity of such experiences. This thesis, then, is no invention of philosophers.

My colleague, in answer, would of course insist that as a fact you and I are now believing that many men exist, and that human experience in its entirety exists, *merely* because, in the long run, we find that this belief is indeed congruous with our current and purely personal experience, and is therefore an expedient idea of ours. But I, in answer, insist that common sense well feels this belief to be indeed from moment to moment expedient, and yet clearly distinguishes between that expediency and the truth which common sense all the while attributes to the belief. The distinction is precisely the one which my fancied illustration of the pragmatist on the witness-stand has suggested. It is a perfectly universal distinction and a commonplace one. Tell me, "This opinion is true," and whatever you are talking about I may agree or disagree or doubt; yet in any case you have stated a momentous issue. But tell me, "I just now find this belief expedient, it feels to me congruous" and you have explicitly given me just a scrap of your personal biography, and have told me no other truth whatever than a truth about the present state of your feelings.

If, however, you emphasize my colleague's wording to the effect that a truth is such because it proves to be an idea that is expedient "in the long run," I once more ask you: *When* does a man experience the whole of the real facts about the "long run"? At the beginning of the long run, when the end is not yet, or at the end, when, perhaps, he forgets, like many older men, what were once the expediencies of his youth? What decides the truth about the long run? My exalted moments, when anything that I like seems true, or my disappointed moments, when I declare that I have always had bad luck? To appeal to the genuinely real "long run" is only to appeal in still another form to a certain ideally fair conspectus of my own whole life, – a conspectus which I,

in my private human experience, never get. Whoever gets the conspectus of my whole life, to see what, in the long run, is indeed for me expedient, – whoever, I say, gets that conspectus, if such a being there indeed is, – is essentially superhuman in his type of consciousness. For he sees what I only get in the form of an idea; namely, the true sense and meaning of my life.

In vain, then, does one try adequately to define the whole of what we mean by truth either in terms of our human feelings of expediency or in terms of our instantaneous thrills of joy in success, or in terms of any other verifications that crumble as the instant flies. All such verifications we use, just as we use whatever perishes. Any such object is a fragment, but we want the whole. Truth is itself a cause, and is largely as one must admit, for us mortals, just now, what we called, in our last lecture, a lost cause – else how should these pragmatists be able thus to imagine a vain thing, and call that truth which is but the crumbling expediency of the moment? Our search for truth is indeed a practical process. The attainment of truth means success. Our verifications, so far as we ever get them, are momentary fragments of that success. But the genuine success that we demand is an ethical success, of precisely the type which all the loyal seek, when they rejoice in giving all for their cause.

VI

But you will now all the more eagerly demand in what sense we can ever get any warrant for saying that we know any truth whatever. In seeking truth we do not seek the mere crumbling successes of the passing instants of human life. We seek a city out of sight. What we get of success within our passing experience is rationally as precious to us as it is, just because we believe that attainment to be a fragment of an essentially superhuman success, which is won in the form of a higher experience than ours, – a conspectus wherein our human experiences are unified. But what warrant have we for this belief?

I will tell you how I view the case. We need unity of life. In recognizing that need my own pragmatism consists. Now, we never find unity present to our human experience in more than a fragmentary shape. We get hints of higher unity. But only the fragmentary unity is won at any moment of our lives. We therefore form ideas – very fallible ideas – of some unity of experience, an unity such as our idea of any science or any art or any united people or of any community or of any other cause, any other union of many human experiences in one, defines. Now, if our ideas are in any case indeed true, then such an unity is as a fact successfully experienced upon some higher level than ours, and is experienced in some conspectus of life which wins what we need, which approves our loyalty, which fulfils our rational will, and which has in its wholeness what we seek. And then we ourselves with all our ideas and strivings are in and of this higher unity of life. Our loyalty to truth is a hint of this unity. Our transient successes are fragments of the true success. But suppose our ideas

about the structure of this higher unity to be false in any of their details. Suppose, namely, any of our causes to be wrongly viewed by us. Then there is still real that state of facts, whatever it is, which, if just now known to us, would show us this falsity of our various special ideas. Now, only an experience, a consciousness of some system of contents, could show the falsity of any idea. Hence this real state of facts, this constitution of the genuine universe, whatever it is, must again be a reality precisely in so far as it is also a conspectus of facts of experience.

We therefore already possess at least one true idea, precisely in so far as we say: "The facts of the world are what they are; the real universe exposes our errors and makes them *errors*." And when we say this, we once more appeal to a conspectus of experience in which ours is included. For I am in error only in case my present ideas about the true facts of the whole world of experience are out of concord with the very meaning that I myself actively try to assign to these ideas. My ideas are in any detail false, only if the very experience to which I mean to appeal, contains in its conspectus contents which I just now imperfectly conceive. In any case, then, the truth is possessed by precisely that whole of experience which I never get, but to which my colleague also inevitably appeals when he talks of the "long run," or of the experiences of humanity in general.

Whatever the truth, then, or the falsity of any of my special convictions about this or that fact may be, the real world, which refutes my false present ideas in so far as they clash with its wholeness, and which confirms them just in so far as they succeed in having significant relations to its unity, – this real world, I say, is a conspectus of the whole of experience. And this whole of experience is in the closest real relation to my practical life, precisely in so far as, for me, the purpose of my life is to get into unity with the whole universe, and precisely in so far as the universe itself is just that conspectus of experience that we all mean to define and to serve whatever we do, or whatever we say.

But the real whole conspectus of experience, the real view of the totality of life, the real expression of that will to live in and for the whole, which every assertion of truth and every loyal deed expresses – well, it must be a conspectus that includes whatever facts are indeed facts, be they past, present, or future. I call this whole of experience an eternal truth. I do not thereby mean, as my colleague seems to imagine, that the eternal first exists, and that then our life in time comes and copies that eternal order. I mean simply that the whole of experience includes all temporal happenings, contains within itself all changes, and, since it is the one whole that we all want and need, succeeds in so far as it supplements all failures, accepts all, even the blindest of services, and wins what we seek. Thus winning it is practically good and worthy.

But if one insists, How do you know all this? I reply: I know simply that to try to deny the reality of this whole of truth is simply to reaffirm it. Any special idea of mine may be wrong, even as any loyal deed may fail, or as any cause

may become, to human vision, a lost cause. But to deny that there is truth, or that there is a real world, is simply to say that the whole truth is that there is no whole truth, and that the real fact is that there is no fact real at all. Such assertions are plain self-contradictions. And on the other hand, by the term "real world," defined as it is for us by our ideal needs, we mean simply that whole of experience in which we live, and in unity with which we alone succeed.

Loyalty, then, has its own metaphysic. This metaphysic is expressed in a view of things which conceives our experience as bound up in a real unity with all experience, – an unity which is essentially good, and in which all our ideas possess their real fulfilment and success. Such a view is true, simply because if you deny its truth you reaffirm that very truth under a new form.

Truth, meanwhile, means, as pragmatism asserts, the fulfilment of a need. But we all need the superhuman, the city out of sight, the union with all life, – the essentially eternal. This need is no invention of the philosophers. It is the need which all the loyal feel, whether they know it or not, and whether they call themselves pragmatists or not. To define this need as pragmatism in its recent forms has done, to reduce truth to expediency, is to go about crying *cash*, *cash*, in a realm where there is no cash of the sort that loyalty demands, that every scientific inquiry presupposes, and that only the unity of the experiences of many in one furnishes.

If we must, then, conceive recent pragmatism under the figure of a business enterprise, – a metaphor which my colleague's phraseology so insistently invites, – I am constrained therefore to sum up its position thus: First, with a winning clearness, and with a most honorable frankness it confesses bankruptcy, so far as the actually needed cash payments of significant truth are concerned. Secondly, it nevertheless declines to go into the hands of any real receiver, for it is not fond of anything that appears too absolute. And thirdly, it proposes simply and openly to go on doing business under the old style and title of the truth. "After all," it says, "are we not, every one of us, fond of credit values?"

But I cannot conceive the position of the loyal to be, in fact, so hopelessly embarrassed as this. The recent pragmatists themselves are, in fact, practically considered very loyal lovers of genuine truth. They simply have mistaken the true state of their accounts. We all know, indeed, little enough. But the loyal man, I think, whether he imagines himself to be a recent pragmatist or not, has a rational right to say this: My cause partakes of the nature of the only truth and reality that there is. My life is an effort to manifest such eternal truth, as well as I can, in a series of temporal deeds. I may serve my cause ill. I may conceive it erroneously. I may lose it in the thicket of this world of transient experience. My every human deed may involve a blunder. My mortal life may seem one long series of failures. But I know that my cause liveth. My true life is hid with the cause and belongs to the eternal.

THE PROBLEM OF TRUTH IN THE LIGHT OF RECENT DISCUSSION

"The Problem of Truth in the Light of Recent Discussion." *William James and Other Essays on the Philosophy of Life* (New York: Macmillan, 1911), chap. 4, pp. 187–254.

An address delivered before the International Congress of Philosophy at Heidelberg, in September, 1908.

The question: What is Truth? is a typical philosophical problem. But it has been by no means at all times equally prominent throughout the history of philosophy. The ages in which it has come to the front have been those wherein, as at present, a keenly critical spirit has been predominant. At such times metaphysical interests are more or less subordinated, for a while, to the problems about method, to logical researches, or to the investigations which constitute a Theory of Knowledge.

Such periods, as we know, have recurred more than once since scholastic philosophy declined. And such a period was that which Kant dominated. But the sort of inquiry into the nature of truth which Kant's doctrine initiated quickly led, at the close of the eighteenth century, to a renewed passion for metaphysical construction. The problem regarding the nature of truth still occupied a very notable place in the doctrine of Fichte. It constituted one of the principal concerns, also, of Hegel's so much neglected and ill-understood "Phänomenologie des Geistes." And yet both in the minds of the contemporaries of Fichte and of Hegel, and still more in those of their later disciples and opponents, the problem of truth went again into the back- ground when compared with the metaphysical, the ethical, and the theological interests which constructive idealism and its opponents, in those days, came to represent. Hence wherever one looks, in the history of philosophical opinion between 1830 and 1870, one sees how the problem of truth, although never wholly neglected, still remained, for some decades, out of the focus of philosophical interest.

But the scene rapidly changed about and after the year 1870. Both the new psychology and the new logic, which then began to flourish, seemed, erelong, almost equally to emphasize the importance of a reconsideration of the problem as to the nature of truth. These doctrines did this, especially because

the question whether logic was henceforth to be viewed as a part of psychology became once more prominent, so soon as the psychological researches then undertaken had attracted the strong interest of the philosophical public. And meanwhile the revived interest in Kant, growing, as it did, side by side with the new psychology, called for a reinterpretation of the problems of the critical philosophy. The reawakening of Idealism, in England and in America, called attention, in its own way, to the same problem. The modern philosophical movement in France, – a movement which was, from the outset, almost equally made up of a devotion to the new psychology and of an interest in the philosophy of the sciences, has coöperated in insisting upon the need of a revision of the theory of truth. And to complete the story of the latest philosophy, recent tendencies in ethics, emphasizing as they have done the problems of individualism, and demanding a far-reaching reconsideration of the whole nature of moral truth, have added the weight of their own, often passionate, interest to the requirements which are here in question.

The total result is that we are just now in the storm and stress of a reëxamination of the whole problem of truth. About this problem the philosophical interest of to-day centers. Consequently, whether you discuss the philosophy of Nietzsche or of mathematics, – whether the *Umwertung alter Werte* or the "class of all classes," – whether Mr. Russell's "Contradiction" or the *Uebermensch* is in question, – or whether none of these things attract you at all, so that your inquiries relate to psychology, or to evolution, or to the concepts of the historical sciences, or to whatever other region of philosophy you please, – always the same general issue has sooner or later to be faced. You are involved in some phase of the problem about the nature of truth.

So much, then, as a bare indication of the historical process which has led us into our present position. I propose, in the present address, to offer an interpretation of some of the lessons that, as I think, we may learn from the recent discussions of the problem whose place in all our minds I have thus indicated.

I

It seems natural to begin such a discussion by a classification of the main motives which are represented by the principal recent theories regarding the nature of truth. In enumerating these motives I need not dwell, in this company, upon those historical inferences and traditions whose presence in recent thought is most easily and universally recognized. That Empiricism, – due to the whole history of the English school, modified in its later expressions by the Positivism of a former generation, and by the types of Naturalism which have resulted from the recent progress of the special sciences, – that, I say, such empiricism has affected our modern discussion of the nature of truth, – this we all recognize. I need not insist upon this fact. Moreover, the place

which Kant occupies in the history of the theory of truth, – that again is something which it is needless here to emphasize. And that the teaching of Fichte and of Hegel, as well as still other idealistic traditions, are also variously represented by present phases of opinion regarding our problem, we shall not now have to rehearse. I presuppose, then, these historical commonplaces. It is not, however, in terms of these that I shall now try to classify the motives to which the latest theories of truth are due.

These recent motives, viewed apart from I those unquestionably real influences of the older traditions of the history of philosophy are, to my mind, three in number:

First, there is the motive especially suggested to us modern men by the study of the history of institutions, by our whole interest in what are called evolutionary processes, and by a large part of our recent psychological investigation. This is the motive which leads many of us to describe human life altogether as a more or less progressive adjustment to a natural environment. This motive incites us, therefore, to judge all human products and all human activities as instruments for the preservation and enrichment of man's natural existence. Of late this motive, whose modern forms are extremely familiar, has directly affected the theory of truth. The result appears in a part, although not in the whole, of what the doctrines known as Instrumentalism, Humanism, and Pragmatism have been of late so vigorously teaching, in England, in America, in Italy, in France, and, in still other forms, in Germany.

From the point of view which this motive suggests, human opinions, judgments, ideas, are part of the effort of a live creature to adapt himself to his natural world. Ideas and beliefs are, in a word, organic functions. And truth, in so far as we men can recognize truth at all, is a certain value belonging to such ideas. But this value itself is simply like the value which any natural organic function possesses. Ideas and opinions are instruments whose use lies in the fact that, if they are the right ones, they preserve life and render life stable. Their existence is due to the same natural causes that are represented in our whole organic evolution. Accordingly, assertions or ideas are true in proportion as they accomplish this their biological and psychological function. The value of truth is itself a biological and psychological value. The true ideas are the ones which adapt us for life as human beings. Truth, therefore, grows with our growth, changes with our needs, and is to be estimated in accordance with our success. The result is that all truth is as relative as it is instrumental, as human as it is useful.

The motive which recent Instrumentalism or Pragmatism expresses, in so far as it takes this view of the nature of truth, is of course in one sense an ancient motive. Every cultivated nation, upon beginning to think, recognizes in some measure such a motive. The Greeks knew this motive, and deliberately connected both the pursuit and the estimate of truth with the art of life in ways whose problematic aspects the Sophists already illustrated. Socrates

and his followers, and later the Stoics as well as the Epicureans, also considered, in their various ways, this instrumental aspect of the nature of truth. And even in the Hindoo Upanishads one can find instances of such humanistic motives influencing the inquiry into the problem of truth. But it is true that the historical science of the nineteenth century, beginning, as it did, with its elaborate study of the history of institutions, and culminating in the general doctrines regarding evolution, has given to this motive an importance and a conscious definiteness such as makes its recent embodiment in Pragmatism a very modern and, in many ways, a novel doctrine about the nature of truth.

II

But closely bound up with this first motive in our recent thinking there is a second motive, which in several ways very strongly contrasts with the first. Yet in many minds these two motives are so interwoven that the writers in question are unaware which motive they are following when they utter their views about the nature of truth. No doubt one may indeed recognize the contrast between these motives, and may, nevertheless, urge good reasons for following in some measure both of them, each in its own way. Yet whoever blindly confuses them is inevitably led into hopeless contradictions As a fact, a large number of our recent pragmatists have never learned consciously to distinguish them. Yet they are indeed easy to distinguish, however hard it may be to see how to bring them into a just synthesis.

This second motive is the same as that which, in ethics, is responsible for so many sorts of recent Individualism. It is the motive which in the practical realm Nietzsche glorified. It is the longing to be self-possessed and inwardly free, the determination to submit to no merely external authority. I need not pause to dwell upon the fact that, in its application to the theory of truth, precisely as in its well-known applications to ethics, this motive is Protean. Every one of us is, I suppose, more or less under its influence.

Sometimes, this motive appears mainly as a skeptical motive. Then it criticizes, destructively, traditional truth and thereupon leaves us empty of all assurances. But sometimes it assumes the shape of a sovereign sort of rationalism, whereby the thinking subject, first rebelling against outer authority, creates his own laws, but then insists that all others shall obey these laws. In other cases, however, it takes the form of a purely subjective idealism, confident of its own but claiming no authority. Or again, with still different results, it consciously unites its ethical with its theoretical interests, calls itself "Personal Idealism," and regards as its main purpose, not only the freeing of the individual from all spiritual bondage, theoretical and practical, but also the winning for him of an inner harmony of life. In general, in its highest as in some of its less successful embodiments, when it considers the sort of truth

that we ought most to pursue, this motive dwells, as Professor Eucken has so effectively taught it to dwell, upon the importance of a *Lebensanschauung* as against the rigidity and the pretended finality of a mere *Weltanschauung*.

But meanwhile, upon occasion, this same motive embodies itself in various tendencies of the sort known as Irrationalism. In this last case, it points out to us how the intelligence, after all, is but a single and a very narrow function of our nature, which must not be allowed to supersede or even too much to dominate the rest of our complex and essentially obscure, if fascinating, life. Perhaps, on the very highest levels of life, as it hereupon suggests to us: *Gefühl ist alles*. If not, then at all events, we have the alternative formula: *Im Anfang war die Tat*. Or, once again, the solving word of the theory of truth is Voluntarism. Truth is won by willing, by creative activities. The doer, or perhaps the deed, not only finds, but *is*, the truth. Truth is not to be copied, but to be created. It is living truth. And life is action.

I have thus attempted to indicate, by well-known phrases, the nature of this second motive, – one whose presence in our recent theories of truth I believe that you will all recognize. Despite the Protean character and (as you will all at once see) the mutually conflicting characters of its expressions, you will observe, I think, its deeper unity, and also its importance as an influence in our age. With us at present it acts as a sort of ferment, and also as an endless source of new enterprises. It awakens us to resist the most various kinds of doctrinal authority, – scientific, clerical, academic, popular. It inspires countless forms of Modernism, both within and without the boundaries of the various confessions of Christendom. As an effective motive, one finds it upon the lowest as also upon the highest levels of our intellectual and moral life. In some sense, as I have said, we all share it. It is the most characteristic and the most problematic of the motives of the modern world. Anarchism often appeals to it; yet the most saintly form of devotion, the most serious efforts for the good of mankind, and our sternest and loftiest spiritual leaders, agree in employing it, and in regarding it as in some sense sacred.

Our age shares this motive with the age of the French Revolution, of the older Idealistic movement, and of the Romantic School. All the more unfortunate, as I think, is the fact that many who glory in the originality of their own recent opinions about the nature of truth, know so little of the earlier history of this motive, read so seldom the lesson of the past, and are thus so ill-prepared to appreciate both the spiritual dignity and the pathetic paradox of this tendency to make the whole problem of truth identical with the problem of the rights and the freedom of the individual.

III

I turn herewith to the third of the motives that I have to enumerate. In its most general form it is a very ancient and familiar motive. It is, indeed, very

different from both of the foregoing. Superficially regarded, it seems, at first sight, less an expression of interests that appear ethical. At heart, however, it is quite as deep a motive as either of the others and it is in fact a profoundly ethical motive as well as a genuinely intellectual one. One may say that, in a sense and to some degree, it pervades the whole modern scientific movement, is present wherever two or three are gathered together for a serious exchange of scientific opinions, and is, in most cases, the one motive that, in scientific assemblies, is more or less consciously in mind whenever somebody present chances to refer to the love of truth, or to the scientific conscience of his hearers.

I have called this third on our list of motives an ancient motive. It is so. Yet in modern times it has assumed very novel forms, and has led to scientific and, in the end, to philosophical enterprises which, until recently, nobody would have thought possible.

It would be unwise at this point to attempt to define this motive in abstract terms. I must first exemplify it. When I say that it is the motive to which the very existence of the exact sciences is due, and when I add the remark that our scientific common sense knows this motive as the fondness for dispassionately weighing evidence, and often simply names it the love of objectivity, I raise more questions in your minds regarding the nature of this motive than at this point I can answer. If, however, anybody suggests, say from the side of some form of recent pragmatism, that I must be referring to the nowadays so deeply discredited motives of a pure "Intellectualism," I repudiate at once the suggestion. The motive to which I refer is intensely practical. Men have lived and died for it, and have found it inestimably precious. I know of no motive purer or sweeter in human life. Meanwhile, it indeed chances to be the motive which has partially embodied itself in Pure Mathematics. And neither the tribe of Nietzsche nor the kindred of the instrumentalists have been able justly to define it.

What I am just now interested to point out is that this motive has entered, in very novel ways, into the formulation of certain modern theories of truth. And when I speak of its most novel forms of expression, the historical process to which I refer is the development of the modern critical study of the foundations of mathematics.

To philosophical students in general the existence of metageometrical researches, which began at the outset of the nineteenth century, has now been made fairly familiar. But the non-Euclidean geometry is but a small fragment of that investigation of the foundations of mathematical truth which went on so rapidly during the nineteenth century. Among the most important of the achievements of the century in this direction were the new definitions of continuity and the irrational numbers, the modern exact theory of limits, and the still infant theory of Assemblages. Most important of all, to my mind, were certain discoveries in the field of Logic of which I shall later say a word. I

mention these matters here as examples of the influence of a motive whose highly technical applications may make it seem to one at a distance hopelessly intellectualistic, but whose relation to the theory of truth is close, just because, as I think, its relation to truly ethical motives is also extremely intimate.

The motive in question showed itself at the outset of the nineteenth century, and later in the form of an increased conscientiousness regarding what should be henceforth accepted as a rigid proof in the exact sciences. The Greek geometers long ago invented the conception of rigid methods of proof and brought their own methods, in certain cases, very near to perfection. But the methods that they used proved to be inapplicable to many of the problems of modern mathematics. The result was that, in the seventeenth and eighteenth centuries, the mathematical sciences rapidly took possession of new realms of truth, but in doing so sacrificed much of the old classic rigidity. Nevertheless, regarded as the instrumentalists now desire us to regard truth, the mathematical methods of the eighteenth century were indeed incomparably more successful in adjusting the work of the physical sciences to the demands of experience than the methods of the Greek geometers had ever been. If instrumentalism had been the whole story of man's interest in truth, the later developments would have been impossible. Nevertheless the modern scientific conscience somehow became increasingly dissatisfied with its new mathematical possessions. It regarded them as imperfectly won. It undertook to question, in a thousand ways, its own methods and its own presuppositions. It learned to reject altogether methods of proof which, for a time, had satisfied the greatest constructive geniuses of earlier modern mathematics. The result has been the development of profoundly novel methods, both of research and of instruction in the exact sciences. These methods have in many ways brought to a still higher perfection the Greek ideal of rigid proof. Yet the same methods have shown themselves to be no mere expressions of a pedantic intellectualism. They have meant clearness, self-possession, and a raising of the scientific conscience to higher levels. Meanwhile, they proved potent both in conquering new realms and in discovering the wonderful connections that we now find linking together types of exact truth which at first sight appeared to be hopelessly diverse.

In close union with the development of these new methods in the exact sciences, and, as I may say, in equally close union with this new scientific conscience, there has gradually come into being a reformed Logic, – a logic still very imperfectly expounded in even the best modern textbooks, and as yet hardly grasped, in its unity, by any one investigator, – but a logic which is rapidly progressing, which is full of beauty, and which is destined, I believe, profoundly to influence, in the near future, our whole philosophy of truth. This new logic appears to offer to us an endless realm for detailed researches. As a set of investigations it is as progressive as any instrumentalist can desire. The best names for it, I think, are the names employed by several different

thinkers who have contributed to its growth. Our American logician, Mr. Charles Peirce, named it, years ago, the Logic of Relatives. Mr. Russell has called it the Logic, or the Calculus, of Relations. Mr. Kempe has proposed to entitle it the Theory of Mathematical Form. One might also call it a new and general theory of the Categories. Seen from a distance, as I just said, it appears to be a collection of highly technical special researches, interesting only to a few. But when one comes into closer contact with any one of its serious researches, one sees that its main motive is such as to interest every truthful and reflective inquirer who really grasps that motive, while the conception of truth which it forces upon our attention is a conception which neither of the other motives just characterized can be said adequately to express.

In so far as the new logic has up to this time given shape to philosophical theories of truth, it in part appears to tend towards what the pragmatists nowadays denounce as Intellectualism. As a fact Mr. Bertrand Russell, the brilliant and productive leader of this movement in England, and his philosophical friend Mr. George Moore, seem to regard their own researches as founded upon a sort of new Realism, which views truth as a realm wholly independent of the constructive activities by which we ourselves find or pursue truth. But the fact that Mr. Charles Peirce, one of the most inventive of the creators of the new logic, is also viewed by the Pragmatists as the founder of their own method, shows how the relation of the new logic to the theory of truth is something that still needs to be made clear. As a fact, I believe that the outcome of the new logic will be a new synthesis of Voluntarism and Absolutism.

What I just now emphasize is, that this modern revision of the concepts of the exact sciences, and this creation of a new logic, are in any case due to a motive which is at once theoretical and ethical. It is a motive which has defined standards of rigidity in proof such as were, until recently, unknown. In this sense it has meant a deepening and quickening of the scientific conscience. It has also seemed, in so far, to involve a rejection of that love of expediency in thinking which is now a favorite watchword of pragmatists and instrumentalists. And when viewed from this side the new logic obviously tends to emphasize some form of absolutism, to reject relativism in thinking, to make sterner requirements upon our love of truth than can be expressed in terms of instrumentalism or of individualism. And yet the motive which lies beneath this whole movement has been, I insist, no barren intellectualism. The novelty of the constructions to which this motive has led, – the break with tradition which the new geometry (for instance) has involved, – such things have even attracted, from a distance, the attention of some of the least exactly trained of the pragmatist thinkers, and have aroused their hasty and uncomprehending sympathy. "This non-Euclidean geometry," they have said, "these novel postulates, these '*freie Schöpfungen des menschlichen Geistes*' (as

Dedekind, himself one of the great creative minds of the new logical movement, has called the numbers), – well, surely these must be instances in favor of *our* theory of truth. Thus, as we should have predicted, novelties appear in what was supposed to be an absolutely fixed region. Thus (as Professor James words the matter), human thought 'boils over', and ancient truths alter, grow, or decay." Yet when modern pragmatists and relationists use such expressions, they fail to comprehend the fact that the new discoveries in these logical and mathematical fields simply exemplify a *more* rigid concept of truth than ever, before the new movement began, had been defined in the minds of the mathematicians themselves. The non-Euclidean geometry, strange to say, is not a discovery that we are any freer than we were before to think as we like regarding the system of geometrical truth. It is one part only of what Hilbert has called the "logical analysis" of our concept of space. When we take this analysis as a whole, it involves a deeper insight than Euclid could possibly possess into the unchangeable necessities which bind together the system of logical relationships that the space of our experience merely exemplifies. Nothing could be more fixed than are these necessities. As for the numbers, which Dedekind called "*freie Schöpfungen*," – well, his own masterpiece of logical theory is a discovery and a rigid demonstration of a very remarkable and thoroughly objective truth about the fundamental relations in terms of which we all of us do our thinking. His proof that all of the endless wealth of the properties of the ordinal numbers follows from a certain synthesis of two of the simplest of our logical conceptions, neither one of which, when taken alone, seems to have anything to do with the conception of order or of number, – this proof, I say, is a direct contribution to a systematic theory of the categories, and, as such, is, to the logical inquirer, a dramatically surprising discovery of a realm of objective truth, which nobody is free to construct or to abandon at his pleasure. If this be relativism, it is the relativism of an eternal system of relations. If this be freedom, it is the divine freedom of a self-determined, but, for that very reason, absolutely necessary fashion of thought and of activity.

Well, – to sum up, – this third motive in modern inquiry has already led us to the discovery of what are, for us, novel truths regarding the fundamental relations upon which all of our thought and all of our activity rest. These newly discovered truths possess an absoluteness which simply sets at naught the empty trivialities of current relativism. Such truth has, in fact, the same sort of relation to the biologically "instrumental" value of our thinking processes as the Theory of Numbers (that "divine science," as Gauss called it) has to the account books of the shopkeeper.

And yet, as I must insist, the motive that has led us to this type of absolutism is no pure intellectualism. And the truth in question is as much a truth about our modes of activity as the purest voluntarism could desire it to be. In brief, there is, I believe, an absolute voluntarism, a theory of the way in which activ-

ities must go on if they go on at all. And, as I believe, just such a theory is that which in future is to solve for us the problem of the nature of truth.

I have illustrated our third motive at length. Shall I now try to name it? Well, I should say that it is at bottom the same motive that lay at the basis of Kant's Critical Philosophy; but it is this motive altered by the influence of the modern spirit. It is the motive which leads us to seek for clear and exact self-consciousness regarding the principles both of our belief and of our conduct. This motive leads us to be content only in case we can indeed find principles of knowledge and of action, – principles, not mere transient expediences, and not mere caprices. On the other hand, this motive bids us decline to accept mere authority regarding our principles. It requires of us freedom along with insight, exactness side by side with assurance, and self-criticism as well as search for the ultimate.

IV

In thus sketching for you these three motives, I have been obliged to suggest my estimate of their significance. But this estimate has so far been wholly fragmentary. Let me next indicate the sense in which I believe that each of these three motives tends, in a very important sense, to throw light upon the genuine theory of truth.

I begin here with the first of the three motives, – namely, with the motive embodied in recent instrumentalism. Instrumentalism views truth as simply the value belonging to certain ideas in so far as these ideas are biological functions of our organisms, and psychological functions whereby we direct our choices and attain our successes.

Wide and manifold are the inductive evidences which the partisans of such theories of truth adduce in support of their theory. There is the evidence of introspection and of the modern psychological theory of the understanding. Opinions, beliefs, ideas, – what are they all but accompaniments of the motor processes whereby, as a fact, our organisms are adjusted to their environment? To discover the truth of an idea, what is that for any one of us but to observe our success in our adjustment to our situation? Knowledge is power. Common sense long ago noted this fact. Empiricism has also since taught us that we deal only with objects of experience. The new instrumentalism adds to the old empiricism simply the remark that we possess truth in so far as we learn how to control these objects of experience. And to this more direct evidence for the instrumental theory of truth is added the evidence derived from the whole work of the modern sciences. In what sense are scientific hypotheses and theories found to be true? Only in this sense, says the instrumentalist, – only in this sense, that through these hypotheses we acquire constantly new sorts of control over the course of our experience. If we turn from scientific to moral truth, we find a similar result. The moral ideas

of any social order are practical plans and practical demands in terms of which this social order endeavors, by controlling the activities of its members, to win general peace and prosperity. The truth of moral ideas lies solely in this their empirical value in adjusting individual activities to social demands, and in thus winning general success for all concerned.

Such are mere hints of the evidences that can be massed to illustrate the view that the truth of ideas is actually tested, and is to be tested, by their experienced workings, by their usefulness in enabling man to control his empirically given situation. If this be the case, then truth is always relative to the men concerned, to their experience, and to their situations. Truth grows, changes, and refuses to be tested by absolute standards. It *happens* to ideas, in so far as they *work*. It belongs to them when one views them as instruments to an end. The result of all this is a relativistic, an evolutionary, theory of truth. For such a view logic is a part of psychology, – a series of comments upon certain common characteristics of usefully working ideas and opinions. Ethical theory is a branch of evolutionary sociology. And in general, if you want to test the truth of ideas and opinions, you must look forward to their workings, not backward to the principles from which they might be supposed to follow, nor yet upwards to any absolute standards which may be supposed to guide them, and least of all to any realm of fixed facts that they are supposed to be required, willy nilly, to copy. Truth is no barren repetition of a dead reality, but belongs, as a quality, to the successful deeds by which we produce for ourselves the empirical realities that we want.

Such is the sort of evidence which my friends, Professor James and Professor Dewey, and their numerous followers, in recent discussion, have advanced in favor of this instrumental, practical, and evolutionary theory of truth. Such are the considerations which, in other forms, Mach has illustrated by means of his history and analyses of the work of modern science.

Our present comment upon this theory must be given in a word. It contains indeed a report of the truth about our actual human life, and about the sense in which we all seek and test and strive for truth, precisely in so far as truth-seeking is indeed a part of our present organic activities. But the sense in which this theory is thus indeed a true account of a vast range of the phenomena of human life is not reducible to the sense which the theory itself ascribes to the term "truth."

For suppose I say, reporting the facts of the history of science: "Newton's theory of gravitation proved to be true, and its truth lay in this: The definition and the original testing of the theory consisted in a series of the organic and psychological functions of the live creature Newton. His theories were for him true in so far as, after hard work, to be sure, and long waiting, they enabled him to control and to predict certain of his own experiences of the facts of nature. The same theories are still true for us because they have successfully guided, and still guide, certain observations and experiences of

the men of to-day." This statement reduces the truth of Newton's theory to the type of truth which instrumentalism demands. But in what sense is my account of this matter itself a true account of the facts of human life? Newton is dead. As mortal man he succeeds no longer. His ideas, as psychological functions, died with him. His earthly experiences ceased when death shut his eyes. Wherein consists to-day, then, the historical truth that Newton ever existed at all, or that the countless other men whom his theories are said to have guided ever lived, or experienced, or succeeded? And if I speak of the men of to-day, in what sense is the statement true that they now live, or have experience, or use Newton's theory, or succeed with it as an instrument? No doubt all these historical and socially significant statements of mine are indeed substantially true. But does their truth consist in my success in using the ideal instruments that I use when I utter these assertions? Evidently I mean, by calling these my own assertions true, much more than I can interpret in terms of my experience of their success in guiding my act.

In brief, the truth that historical events ever happened at all; the truth that there ever was a past time, or that there ever will be a future time; the truth that anybody ever succeeds, except in so far as I myself, just now, in the use of these my present instruments for the transient control of my passing experience chance to succeed; the truth that there is any extended course of human experience at all, or any permanence, or any long-lasting success, – well, all such truths, they are indeed true, but their truth cannot possibly consist in the instrumental value which any man ever experiences as belonging to any of his own personal ideas or acts. Nor can this truth consist in anything that even a thousand or a million men can separately experience, each as the success of his own ideal instruments. For no one man experiences the success of any man but himself, or of any instruments but his own; and the truth, say, of Newton's theory consists, by hypothesis, in the perfectly objective fact that generations of men have really succeeded in guiding their experience by this theory. But that this is the fact no man, as an individual man, ever has experienced or will experience under human conditions.

When an instrumentalist, then, gives to us his account of the empirical truth that men obtain through using their ideas as instruments to guide and to control their own experience, his account of human organic and psychological functions may be, – yes, is, – as far as it goes, true. But if it is true at all, then it is true as an account of the characters actually common to the experience of a vast number of men. It is true, if at all, as a report of the objective constitution of a certain totality of facts which we call human experience. It is, then, true in a sense which no man can ever test by the empirical success of his own ideas as his means of controlling his own experiences. Therefore the truth which we must ascribe to instrumentalism, if we regard it as a true doctrine at all, is precisely a truth, not in so far as instrumentalism is itself an instrument for helping on this man's or that man's way of controlling his

experience. If instrumentalism is true, it is true as a report of facts about the general course of history, of evolution, and of human experience, – facts which transcend every individual man's experience, verifications, and successes. To make its truth consist in the mere sum of the various individual successes is equally vain, unless indeed that sum is a fact. But no individual man ever experiences that fact.

Instrumentalism, consequently, expresses no motive which by itself alone is adequate to constitute any theory of truth. And yet, as I have pointed out, I doubt not that instrumentalism gives such a substantially true account of man's natural functions as a truth seeker. Only the sense in which instrumentalism is a true account of human life is opposed to the adequacy of its own definition of truth. The first of our three motives is, therefore, useful only if we can bring it into synthesis with other motives. In fact it is useless to talk of the success of the human spirit in its efforts to win control over experience, unless there is indeed a human spirit which is more than any man's transient consciousness of his own efforts, and unless there is an unity of experience, an unity objective, real, and supratemporal in its significance.

V

Our result so far is that man indeed uses his ideas as means of controlling his experience, and that truth involves such control, but that truth cannot be defined solely in terms of our personal experience of our own success in obtaining this control.

Hereupon the second of the motives which we have found influencing the recent theories of truth comes to our aid. If instrumentalism needs a supplement, where are we, the individual thinkers, to look for that supplement, except in those inner personal grounds which incline each of us to make his own best interpretations of life precisely as he can, in accordance with his own will to succeed, and in accordance with his individual needs?

To be sure, as one may still insist, we are always dealing with live human experience, and with its endless constraints and limitations. And when we accept or reject opinions, we do so because, at the time, these opinions seem to us to promise a future empirical "working," a successful "control" over experience, – in brief, a success such as appeals to live human beings. Instrumentalism in so far correctly defines the nature which truth possesses in so far as we ever actually verify truth. And of course we always believe as we do because we are subject to the constraint of our present experience. But since we are social beings, and beings with countless and varied intelligent needs, we constantly define and accept as valid very numerous ideas and opinions whose truth we do not hope personally to verify. Our act in accepting such unverified truths is (as Professor James states the case) essentially similar to the act of the banker in accepting credit values instead of cash.

A note or other evidence of value is good if it *can* be turned into cash at some agreed time, or under specified conditions. Just so, an idea is true, not merely at the moment when it enables somebody to control his own experience. It is true if, under definable conditions which, as a fact, you or I may never verify, it *would* enable some human being whose purposes agree with ours to control his own experience. If we personally do not verify a given idea, we can still accept it then upon its credit value. We can accept it precisely as paper, which cannot now be cashed, is accepted by one who regards that paper as, for a given purpose, or to a given extent, equivalent to cash. A bond, issued by a government, may promise payment after fifty years. The banker may to-day accept such a bond as good, and may pay cash for it, although he feels sure that he personally will never live to see the principal repaid by the borrower.

Now, as Professor James would say, it is in this sense that our ideas about past time, and about the content of other men's minds, and about the vast physical world, "with all its stars and milky ways," are accepted as true. Such ideas have for us credit values. We accept these ideas as true because we need to trade on credits. Borrowed truth is as valuable in the spiritual realm as borrowed money is in the commercial realm. To believe a now unverified truth is simply to say: "I accept that idea, upon credit, as equivalent to the cash payments in terms of live experience which, as I assert, I could get in case I had the opportunity."

And so much it is indeed easy to make out about countless assertions which we all accept. They are assertions about experience, but not about our present experience. They are made under various constraints of convention, habit, desire, and private conviction, but they are opinions whose truth is for us dependent upon our personal assent and acquiescence.

Herewith, however, we face what is, for more than one modern theory of truth, a very critical question. Apparently it is one thing to say: "I accept this opinion upon credit," and quite another thing to say: "The truth of this opinion consists, solely and essentially, in the fact that it is credited by me." In seeming, at least, it is one thing to assert: "We trade upon credit; we deal in credits," and quite another thing to say: "There is no value behind this bond or behind this bit of irredeemable paper currency, except its credit value." But perhaps a modern theory of truth may decline to accept such a difference as ultimate. Perhaps this theory may say: The truth *is* the credit. As a fact, a vast number of our human opinions – those, for instance, which relate to the past, or to the contents of other men's minds – appear, within the range of our personal experience, as credits whose value we, who believe the opinions, cannot hope ever to convert into the cash of experience. The banker who holds the bond not maturing within his own lifetime can, after all, if the bond is good, sell it to-day for cash. And that truth which he can personally and empirically test whenever he wants to test, is enough to warrant his act in

accepting the credit. But I, who am confident of the truths of history, or of geology, or of physics, and who believe in the minds of other men, – I accept as valid countless opinions that are for me, in my private capacity and from an empirical point of view, nothing but irredeemable currency. In vain do I say: "I *could* convert these ideas into the cash of experience *if* I were some other man, or *if* I were living centuries ago instead of to-day." For the question simply recurs: In what sense are these propositions about my own possible experience true when I do not test their truth, – yes, true although I, personally *cannot* test their truth? These credits, irredeemable in terms of the cash of my experience, – wherein consists their true credit value?

Here one apparently stands at the parting of the ways. One can answer this question by saying: "The truth of these assertions (or their falsity, if they are false) belongs to them whether I credit them or no, whether I verify them or not. Their truth or their falsity is their own character and is independent of my credit and my verification." But to say this appears to be, after all, just the intellectualism which so many of our modern pragmatists condemn. There remains, however, one other way. One can say: "The truth of the unverified assertions *consists simply in the fact that*, for our own private and individual ends, *they are credited*. Credit is relative to the creditor. If he finds that, on the whole, it meets his purpose to credit, he credits. And there is no truth, apart from present verifications, except this truth of credit." In other words, that is true for me which I find myself accepting as my way of reacting to my situation.

This, I say, is a theory of truth which can be attempted. Consider what a magnificent freedom such a theory gives to all of us. Credit is relative to the creditor. To be sure, if ever the day of reckoning should come, one would be subject, at the moment of verification, to the constraints of experience. At such times, one would either get the cash or would not get it. But after all very few of our ideas about this great and wonderful world of ours ever are submitted to any such sharp tests. History and the minds of other men, – well, our personal opinions about these remain credits that no individual amongst us can ever test for himself. As your world is mainly made up of such things, your view of your world remains, then, subject to your own needs. It ought to be thus subject. There is no absolute truth. There is only the truth that you need. Enter into the possession of your spiritual right. Borrow Nietzsche's phraseology. Call the truth of ordinary intellectualism mere *Sklavenwahrheit*. It pretends to be absolute; but only the slaves believe in it. "Henceforth," so some Zarathustra of a new theory of truth may say, "I teach you *Herrenwahrheit*." Credit what you choose to credit. Truth is made for man, not man for truth. Let your life "boil over" into new truth as much as you find such effervescence convenient. When, apart from the constraints of present verification, and apart from mere convention, I say: "This opinion of mine is true," I mean simply: "To my mind, lord over its own needs, this

assertion now appears expedient." Whenever my expediency changes, my truth will change.

But does anybody to-day hold just *this* theory of truth? I hesitate to make accusations which some of my nearest and dearest friends may repudiate as personally injurious. But this I can say: I find a great many recent theorists about truth talking in just this spirit so long as they feel free to glorify their spiritual liberty, to amuse their readers with clever assaults upon absolutism, and to arouse sympathy by insistence upon the human and the democratic attractiveness of the novel views of truth that they have to advance. Such individualism, such capriciousness, is in the air. Our modern theorists of truth frequently speak in this way. When their expressions of such views are criticized, they usually modify and perhaps withdraw them. What, as individuals, such teachers really mean, I have no right to say. Nobody but themselves can say; and some of them seem to say whatever they please. But this I know: Whoever identifies the truth of an assertion with his own individual interest in making that assertion may be left to bite the dust of his own confusion in his own way and time. The outcome of such essential waywardness is not something that you need try to determine through controversy. It is self-determined. For in case I say to you: "The sole ground for my assertions is this, that I please to make them," – well, at once I am defining exactly the attitude which we all alike regard as the attitude of one who chooses *not* to tell the truth. And if, hereupon, I found a theory of truth upon generalizing such an assertion, – well, I am defining as truth-telling precisely that well-known practical attitude which is the contradictory of the truth-telling attitude. The contrast is not one between intellectualism and pragmatism. It is the contrast between two well-known attitudes of will, – the will that is loyal to truth as an universal ideal, and the will that is concerned with its own passing caprices. If I talk of truth, I refer to what the truth-loving sort of will seeks. If hereupon I define the true as that which the individual personally views as expedient in opinion or in assertion, I contradict myself, and may be left to my own confutation. For the position in which I put myself, by this individualistic theory of truth, is closely analogous to the position in which Epimenides the Cretan, the hero of the fallacy of the liar, was placed by his own so famous thesis.

VI

And yet, despite all this, the modern assault upon mere intellectualism is well founded. The truth of our assertions is indeed definable only by taking account of the meaning of our own individual attitudes of will, and the truth, whatever else it is, is at least instrumental in helping us towards the goal of all human volition. The only question is whether the will really means to aim at doing something that has a final and eternal meaning.

Herewith I suggest a theory of truth which we can understand only in case we follow the expressions of the third of the three modern motives to which I have referred. I have said that the new logic and the new methods of reasoning in the exact sciences are just now bringing us to a novel comprehension of our relation to absolute truth. I must attempt a very brief indication as to how this is indeed the case.

I have myself long since maintained that there is indeed a logic of the will, just as truly as there is a logic of the intellect. Personally, I go further still. I assert: all logic is the logic of the will. There is no pure intellect. Thought is a mode of action, a mode of action distinguished from other modes mainly by its internal clearness of self-consciousness, by its relatively free control of its own procedure, and by the universality, the impersonal fairness and obviousness of its aims and of its motives. An idea in the consciousness of a thinker is simply a present consciousness of some expression of purpose, – a plan of action. A judgment is an act of a reflective and self-conscious character, an act whereby one accepts or rejects an idea as a sufficient expression of the very purpose that is each time in question. Our whole objective world is meanwhile defined for each of us in terms of our ideas. General assertions about the meaning of our ideas are reflective acts whereby we acknowledge and accept certain ruling principles of action. And in respect of all these aspects of doctrine I find myself at one with recent voluntarism, whether the latter takes the form of instrumentalism, or insists upon some more individualistic theory of truth. But for my part, in spite, or in fact because of this my voluntarism, I cannot rest in any mere relativism. Individualism is right in saying, "I will to credit this or that opinion." But individualism is wrong in supposing that I can ever be content with my own will in as far as it is merely an individual will. The will to my mind is to all of us nothing but a thirst for complete and conscious self-possession, for fullness of life. And in terms of this its central motive, the will defines the truth that it endlessly seeks as a truth that possesses completeness, totality, self-possession, and therefore absoluteness. The fact that, in our human experience, we never meet with any truths such as completely satisfy our longing for insight, this fact we therefore inevitably interpret, not as any defect in the truth, but as a defect in our present state of knowledge a limitation due to our present type of individuality. Hence we acknowledge a truth which transcends our individual life. Our concepts of the objectively real world, our ethical ideals of conduct, our estimates of what constitutes the genuine worth of life, – all these constructions of ours are therefore determined by the purpose to conform our selves to absolute standards We will the eternal. We define the eternal. And this we do whenever we talk of what we call genuine facts or actualities, or of the historical content of human experience, or of the physical world that our sciences investigate. If we try to escape this inner necessity of our whole voluntary and self-conscious life, we simply contradict

ourselves. We can define the truth even of relativism only by asserting that relativism is after all absolutely true. We can admit our ignorance of truth only by acknowledging the absoluteness of that truth of which we are ignorant. And all this is no caprice of ours. All this results from a certain necessary nature of our will which we can test as often as we please by means of the experiment of trying to get rid of the postulate of an absolute truth. We shall find that, however often we try this experiment, the denial that there is any absolute truth simply leads to its own denial, and reinstates what it denies.

The reference that I a little while since made to our assertions regarding the past, and regarding the minds of other men, has already suggested to us how stubbornly we all assert certain truths which, for every one of us, transcend empirical verification, but which we none the less regard as absolutely true. If I say: "There never was a past," I contradict myself, since I assume the past even in asserting that a past never was. As a fact our whole interpretation of our experience is determined, in a sense akin to that which Kant defined, by certain modes of our own activity, whose significance is transcendental, even while their whole application is empirical. These modes of our activity make all our empirical sciences logically possible. Meanwhile it need not surprise us to find that Kant's method of defining these modes of our activity was not adequate, and that a new logic is giving us, in this field, new light. The true nature of these necessary modes of our activity becomes most readily observable to us in case we rightly analyze the methods and concepts, not of our own empirical, but rather of our mathematical sciences. For in these sciences our will finds its freest expression. And yet for that very reason in these sciences the absoluteness of the truth which the will defines is most obvious. The new logic to which I refer is especially a study of the logic of mathematics.

VII

That there are absolutely true propositions, the existence of the science of pure mathematics proves. It is indeed the case that, as Russell insists, the propositions of pure mathematics are (at least in general) hypothetical propositions. But the hypothetical character of the propositions of pure mathematics does not make the truth that a certain mathematically interesting consequent follows from a certain antecedent, in any way less than absolutely true. The assertion, "*a* implies *b*," where *a* and *b* are propositions, may be an absolutely true assertion; and, as a fact, the hypothetical assertions of pure mathematics possess this absolutely true character. Now it is precisely the nature and ground of this absoluteness of purely mathematical truth upon which recent research seems to me to have thrown a novel light. And the light which has appeared in this region seems to me to be destined to reflect itself anew upon all regions and types of truth, so that empirical and contingent, and historical

and psychological and ethical truth, different as such other types of truth may be from mathematical truth, will nevertheless be better understood, in future, in the light of the newer researches into the logic of pure mathematics. I can only indicate, in the most general way, the considerations which I here have in mind.

At the basis of every mathematical theory, – as, for instance, at the basis of pure geometry, or pure number theory, – one finds a set of fundamental concepts, the so-called "indefinables" of the theory in question, and a set of fundamental "propositions," the so-called "axioms" of this theory. Modern study of the logic of pure mathematics has set in a decidedly novel light the question: What is the rational source, and what is the logical basis of these primal concepts and of these primal propositions of mathematical theory? I have no time here to deal with the complications of the recent discussion of this question. But so much I can at once point out: there are certain concepts and certain propositions which possess the character of constituting the doctrine which may be called, in the modern sense, Pure Logic. Some of these concepts and propositions were long ago noted by Aristotle. But the Aristotelian logic actually took account of only a portion of the concepts of pure logic, and was able to give, of these concepts, only a very insufficient analysis. There is a similar inadequacy about the much later analysis of the presuppositions of logic which Kant attempted. The theory of the categories is in fact undergoing, at present, a very important process of reconstruction. And this process is possible just because we have at present discovered wholly new means of analyzing the concepts and propositions in question. I refer (as I may in passing state) to the means supplied by modern Symbolic Logic.

Well, the concepts of pure logic, when once defined, constitute an inexhaustible source for the constructions and theories of pure mathematics A set of concepts and of propositions such as can be made the basis of a mathematical theory is a set possessing a genuine and unquestionable significance if, and only if, these concepts and these propositions can be brought into a certain definite relation with the concepts and propositions of pure logic. This relation may be expressed by saying that if the conditions of general logical theory are such as to imply the valid possibility of the mathematical definitions and constructions in question, then – but only then – are the corresponding mathematical theories at once absolutely valid and significant. In brief, pure mathematics consists of constructions and theories based wholly upon the conceptions and propositions of pure logic.

The question as to the absoluteness of mathematical truth hereupon reduces itself to the question as to the absoluteness of the truths of pure logic.

Wherein, however, consists this truth of pure logic? I answer, at once, in my own way. Pure logic is the theory of the mere form of thinking. But what is thinking? Thinking, I repeat, is simply our activity of willing precisely in so far as we are clearly conscious of what we do and why we do it. And

thinking is found by us to possess an absolute form precisely in so far as we find that there are certain aspects of our activity which sustain themselves even in and through the very effort to inhibit them. One who says: "I do not admit that for me there is any difference between saying yes and saying no," – says "no," and distinguishes negation from affirmation, even in the very act of denying this distinction. Well, affirmation and negation are such self-sustaining forms of our will activity and of our thought activity. And such self-sustaining forms of activity determine absolute truths. For instance, it is an absolute truth that there is a determinate difference between the assertion and the denial of a given proposition, and between the doing and the not doing of a given deed. Such absolute truths may appear trivial enough. Modern logical theory is for the first time making clear to us how endlessly wealthy in consequences such seemingly trivial assertions are.

The absoluteness of the truths of pure logic is shown through the fact that you can test these logical truths in this reflective way. They are truths such that to deny them is simply to reassert them under a new form. I fully agree, for my own part, that absolute truths are known to us only in such cases as those which can be tested in this way. I contend only that recent logical analysis has given to us a wholly new insight as to the fruitfulness of such truths.

VIII

An ancient example of a use of that way of testing the absoluteness of truth which is here in question is furnished by a famous proof which Euclid gave of the theorem, according to which there exists no last prime number in the ordinal sequence of the whole numbers. Euclid, namely, proved this theorem by what I suppose to be one device whereby individual instances of absolute truths are accessible to men. He proved the theorem by showing that the denial of the theorem implies the truth of the theorem. That is, if I suppose that there is a last prime number, I even thereby provide myself with the means of constructing a prime number, which comes later in the series of whole numbers than the supposed "last" prime, and which certainly exists just as truly as the whole numbers themselves exist. Here, then, is one classic instance of an absolute truth.

To be sure Euclid's theorem about the prime numbers is a hypothetical proposition. It depends upon certain concepts and propositions about the whole numbers. But the equally absolute truth that the whole numbers themselves form an endless series, with no last term, has been subjected, in recent times, to wholly new forms of reexamination by Dedekind, by Frege, and by Russell. The various methods used by these different writers involve substantially the same sort of consideration as that which Euclid already applied to the prime numbers. There are certain truths which you cannot deny without

denying the truth of the first principles of pure logic. But to deny these latter principles is to reassert them under some other and equivalent form. Such is the common principle at the basis of the recent reëxamination of the concept of the whole numbers. Dedekind, in showing that the existence of the dense ordinal series of the rational numbers implies the existence of the Dedekind *Schnitte* of this series, discovered still another absolute, although of course hypothetical, truth which itself implies the truth of the whole theory of the so-called real numbers. Now all such discoveries are indeed revelations of absolute truth in precisely this sense, that at the basis of all the concepts and propositions about number there are concepts and propositions belonging to pure logic; while if you deny these propositions of pure logic, you imply, by this very denial, the reassertion of what you deny. To discover this fact, to see that the denial of a given proposition implies the reassertion of that proposition, is not, as Kant supposed, something that you can accomplish, if at all, then only by a process of mere "analysis." On the contrary, Euclid's proof as to the prime numbers, and the modern exact proofs of the fundamental theorems of mathematics, involve, in general, a very difficult synthetic process, – a construction which is by no means at first easy to follow. And the same highly synthetic constructions run through the whole of modern logic.

Now once again what does one discover when he finds out such absolute truths? I do not believe, as Russell believes, that one in such cases discovers truths which are simply and wholly independent of our constructive processes. On the contrary, what one discovers is distinctly what I must call a voluntaristic truth, – a truth about the creative will that thinks the *truth*. One discovers, namely, that our constructive processes, viewed just as activities, possess a certain absolute nature and conform to their own self-determined but, for that very reason, absolute laws. One finds out in such cases what one must still, with absolute necessity, do under the presupposition that one is no longer bound by the constraints of ordinary experience, but is free, as one is in pure mathematics free, to construct whatever one can construct. The more, in such cases, one deals with what indeed appear to be, in one aspect, "*freie Schöpfungen des menschlichen Geistes*," the more one discovers that their laws, which are the fundamental and immanent laws of the will itself, are absolute. For one finds what it is that one must construct even if one denies that, in the ideal world of free construction which one is seeking to define, that construction has a place. In brief, all such researches illustrate the fact that while the truth which we acknowledge is indeed relative to the will which acknowledges that truth, still what one may call the pure form of willing is an absolute form, a form which sustains itself in the very effort to violate its own laws. We thus find out absolute truth, but it is absolute truth about the nature of the creative will in terms of which we conceive all truths.

Now it is perfectly true that such absolute truth is not accessible to us in the empirical world, in so far as we deal with individual phenomena. But it

is also true that we all of us conceive the unity of the world of experience – the meaning, the sense, the connection of its facts – in terms of those categories which express precisely this very form of our creative activity. Hence, although every empirical truth is relative, all relative truth is inevitably defined by us as subject to conditions which themselves are absolute. This, which Kant long ago maintained, gets a very new meaning in the light of recent logic, – a far deeper meaning, I think, than Kant could conceive.

In any case, the new logic, and the new mathematics, are making us acquainted with absolute truth, and are giving to our knowledge of this truth a clearness never before accessible to human thinking. And yet the new logic is doing all this in a way that to my mind is in no wise a justification of the intellectualism which the modern instrumentalists condemn. For what we hereby learn is that all truth is indeed relative to the expression of our will, but that the will inevitably determines for itself forms of activity which are objectively valid and absolute, just because to attempt to inhibit these forms is once more to act, and is to act in accordance with them. These forms are the categories both of our thought and of our action. We recognize them equally whether we consider, as in ethics, the nature of reasonable conduct, or, as in logic, the forms of conceptual construction, or, as in mathematics, the ideal types of objects that we can define by constructing, as freely as possible, in conformity with these forms. When we turn back to the world of experience, we inevitably conceive the objects of experience in terms of our categories. Hence the unity and the transindividual character which rightly we assign to the objects of experience. What we know about these objects is always relative to our human needs and activities. But all of this relative knowledge is – however provisionally – defined in terms of absolute principles. And that is why the scientific spirit and the scientific conscience are indeed the expression of motives, which you can never reduce to mere instrumentalism, and can never express in terms of any individualism. And that is why, wherever two or three are gathered together in any serious moral or scientific enterprise, they believe in a truth which is far more than the mere working of any man's ephemeral assertions.

In sum, an absolute truth is one whose denial implies the reassertion of that same truth. To us men, such truths are accessible only in the realm of our knowledge of the forms that predetermine all of our concrete activities. Such knowledge we can obtain regarding the categories of pure logic and also regarding the constructions of pure mathematics. In dealing, on the other hand, with the concrete objects of experience, we are what the instrumentalists suppose us to be, namely, seekers for a successful control over this experience. And as the voluntarists also correctly emphasize, in all our empirical constructions, scientific and practical, we express our own individual wills and seek such success as we can get. But there remains the fact that in all these constructions we are expressing a will which, as logic and pure mathematics

teach us, has an universal absolute nature, – the same in all of us. And it is for the sake of winning some adequate expression of this our absolute nature, that we are constantly striving in our empirical world for a success which we never can obtain at any instant, and can never adequately define in any merely relative terms. The result appears in our ethical search for absolute standards, and in our metaphysical thirst for an absolute interpretation of the universe, – a thirst as unquenchable as the over-individual will that expresses itself through all our individual activities is itself world-wide, active, and in its essence absolute.

In recognizing that all truth is relative to the will, the three motives of the modern theories of truth are at one. To my mind they, therefore, need not remain opposed motives. Let us observe their deeper harmony, and bring them into synthesis. And then what I have called the trivialities of mere instrumentalism will appear as what they are – fragmentary hints, and transient expressions, of that will whose life is universal, whose form is absolute, and whose laws are at once those of logic, of ethics, of the unity of experience, and of whatever gives sense to life.

Tennyson, in a well-known passage of his "In Memoriam," cries:

> "Oh living Will that shalt endure
> When all that seems shall suffer shock,
> Rise in the spiritual rock,
> Flow through our deeds and make them pure."

That cry of the poet was an expression of moral and religious sentiment and aspiration; but he might have said essentially the same thing if he had chosen the form of praying: Make our deeds logical. Give our thoughts sense and unity. Give our Instrumentalism some serious unity of eternal purpose. Make our Pragmatism more than the mere passing froth of waves that break upon the beach of triviality. In any case, the poet's cry is an expression of that Absolute Pragmatism, of that Voluntarism, which recognizes all truth as the essentially eternal creation of the Will. What the poet utters is that form of Idealism which seems to me to be indicated as the common outcome of all the three motives that underlie the modern theory of truth.

ERROR AND TRUTH

Josiah Royce, "Error and Truth." *Encyclopedia of Religion and Ethics,* ed. James Hastings (New York: Charles Scribner's Sons, 1912), vol. 5, pp. 366–373.

I. Introduction.

Both in its philosophical and in its popular acceptation the word 'error' is applied to false opinions. But the popular usage also gives to the term a still wider meaning, whereby it includes not only false opinions, but numerous forms of practical failure, and of defective conduct, whose relations to conscious beliefs are by no means constant or easily discoverable. The derivation of the word illustrates the naturalness of associating the conception of false opinion with the idea of some such act as wandering, or straying, or missing the way. It seems, therefore, as if a first approach to a sharper definition of 'error' would be aided by clearly distinguishing between the practical and the theoretical applications, and then confining the philosophical use of the term, so far as possible, to theoretical errors. But we shall find it impossible to define even theoretical error without reference to some genuinely practical considerations. However much we try to avoid popular confusions, we shall be led in the end to a concept of error which can be stated only in teleological terms, and which involves the idea of action for an end, and of a certain defect in the carrying out of such action.

The present article, after distinguishing, as far as possible, the concept of theoretical errors, or of false opinions, from the popular concept of practical errors, and after stating some of the best known views regarding what a false opinion is, will seek to indicate the nature of a solution of the problem in terms of a doctrine about the relation of the cognitive to the volitional processes.

2. *Practical errors and false opinions.* – When one emphasizes the practical aspect of an error, one sometimes makes use of the more drastic word 'blunder.' A blunder is something which involves serious maladjustment, defect in conduct. Errors in the sense of blunders may be due to false opinions, or may even very largely consist of such. On the other hand, they need not involve false opinions, and *must* involve actions which do not attain their goal. These actions may be only partly voluntary; but the relation of their defective aspects to the accompanying voluntary processes is what makes us call them errors. Thus, we speak of the error or blunder of the marksman who misses his mark; of the player who fails to score, or who

permits his opponent to score when the game calls for some device for hindering the opponent from scoring. We speak of the musician's error when he sings or plays a false note. Such errors may, but often do not, result from, or accompany, false opinions or misjudgments. Thus one may fail as marksman, as player, or as musician, either through misjudgments or through defects of physical training, of temporary condition, of mood, or of attention – defects which may involve no false opinions whatsoever.

In the moral realm, the relations between such practical errors on the one hand and false opinions on the other are especially momentous and intricate. Here, in fact, the theory of moral error involves all the main problems about the relations between knowledge and action. A sin is very generally called an error. 'We have erred and strayed from thy ways like lost sheep.' The error is, first of all, practical. It has also some relation to knowledge. Yet, since sin appears to depend upon some degree of knowledge of right, the 'error' in question does not merely result from a false opinion about what one's duty is. On the other hand, that sin involves 'unwisdom,' and so does in some respect depend upon false opinions, is very generally asserted. Any careful discussion of those practical errors which have a moral significance will, therefore, show that it is no merely accidental confusion which has led us to our use of a word derived from our experience of wanderings from the right path as a term which is also to be applied to false opinions. Opinions certainly express themselves in actions; and voluntary actions are guided by opinions. The resulting relations of cognition and volition, especially in the moral world, are amongst the most complex and intimate which are known to us anywhere. They are relations which we can neither ignore nor wholly disentangle. Hence the clear separation of theoretical error and practical error, at least in the moral world, is impossible. For sin involves both theoretical and practical defects.

We can, however, make some approach to such a separation of the theoretical and practical aspects of error if we turn for aid to a very different realm, namely, formal logic. The distinction between true and false propositions involves certain well-known general relations, such as formal logic considers and analyzes. We may use these relations for what they are worth in attempting to define what a false opinion is. Having thus laid a basis for further analysis, we may attempt to clear the way through some of the more complex regions of the problem of error.

The distinction between true opinion and false opinion obviously depends upon, but also is obviously not identical with, the formal logical distinction between true and false propositions. This close relation and important difference between these two distinctions appear upon a brief study of the considerations which formal logic employs in dealing with the concepts of truth and falsity. True and false are, for the formal logician, predicates belonging to propositions, quite apart from any question as to whether

anybody believes or asserts those propositions. With regard to the predicates 'true' and 'false,' formal logic uses, upon occasion, the following well-known principles, which we may here provisionally accept as a basis for further inquiry: (1) every proposition (supposing its meaning to be precise) is either true or false, and cannot be both true and false; (2) to every proposition there corresponds a determinate proposition which is the contradictory of the first proposition; (3) the relation of contradictories is reciprocal or 'symmetrical'; (4) of two contradictory propositions, one is true and the other is false. These may be here regarded, if one chooses, merely as defining principles, explaining what one means by propositions, and how one proposes to use the logical predicates 'true' and 'false'.

Granting these purely formal principles, of which all exact reasoning processes make constant use, it is obvious that propositions taken collectively as a system constitute an ideal realm wherein to every truth there uniquely corresponds its contradictory falsity, and to every false proposition its contradictory true proposition. The realms of truth and falsity are thus formally inseparable. To know that a given proposition is false is to know that the corresponding contradictory is true, and *vice versa*. Omniscience regarding the realm of truth would, therefore, equally involve knowing true propositions as true and false propositions as false; nor could the one sort of knowledge be defined or real without the other.

But no such formal logical necessity appears to connect true opinion and error. No one can know that $2 + 2 = 4$ is true without thereby knowing that $2 + 2 \neq 4$ (that is, the contradictory of the former assertion) is false. But we can conceive of a computer who should never make any errors in computation; and such a computer might even be supposed so perfect, in the possession of some superhuman infallibility of computation, as not even to know what it would be to err in his additions. We ourselves, when we use the assertion $2 + 2 = 4$ as an example of a peculiarly obvious proposition of computation, find this bit of summation one about which it is rare or difficult for a man 'in his sober senses' to err. Yet for us the knowledge of the truth of the proposition $2 + 2 = 4$ is logically inseparable from the knowledge of the falsity of the contradictory of this proposition.

In sum, then, true and false propositions are logically inseparable. To possess a knowledge of truth is, therefore, inseparable from the possession of a knowledge of what falsity is, and of what false propositions mean. But a being can be supposed to know truth and falsity, and their distinctions and relations, without having any tendency to fall a prey to error. At all events, no purely formal logical reasons, such as for the moment concern us, can be given for supposing that a being who is capable of knowing truth should be capable of falling into error. The more concrete distinction between true opinion and error must, therefore, be different from the formal logical difference between truth and falsity. The latter may be viewed as a logically

necessary distinction between inseparable objects. The former must be due to motives or causes, and must imply mental tendencies and situations of which formal logic, taken in its deliberate abstraction from the fullness of life, gives no account.

The concept of a false opinion is thus obviously distinct from that of a false proposition, and not every true opinion requires that the corresponding false opinion should be held by somebody. It is the purpose of advancing science, of education, of the propagation of truth, to diminish and, so far as may be, 'to banish error' from the minds of men. If this purpose were somehow miraculously attained, there would be as many false propositions in the formal logician's ideal realm of truth and falsity as there ever were; but human errors would have ceased.

3. *The leading definitions of error.* – To define false opinion, hereupon, as the acceptance or the mistaking of false propositions for true ones, or of true for false ones, is a familiar device of philosophers, but it throws no light upon the real nature of error. For, to mistake a falsity for a truth, to accept a false opinion as true – what is this but simply to make a mistake, or to hold a false opinion? This supposed definition is but a tautology. Not thus is the nature of error to be clarified. Further light upon the subject can be obtained only through (1) defining more exactly the distinction between true and false propositions; and (2) showing upon what further distinctions the conception of error depends. Some of the best known efforts to accomplish this result must next be summarily stated and criticized.

(i.) *The* '*Correspondence theory of truth and falsity*' and the definitions of error based upon it deserve to be stated, because they are familiar, and because they have formed the starting-point for supplementary doctrines and definitions and for corrections. According to the view now in question, a proposition is true if it reports, or describes, or portrays 'facts as they are.' The emphasis is laid upon the 'as.' A true idea 'corresponds' in its structure to the thing, or reality, or fact of which it is a true idea; a true proposition is one which asserts that an idea does thus correspond to the facts, when it actually so corresponds. Or, again, if the account given by a proposition conforms to the structure of the facts of which it attempts to furnish an ideal portrayal, the proposition is true. Thus, a proposition may relate to the number in a real flock of sheep. In this case an idea, gained by counting the sheep, is first formed, and then the assertion is made that this numerical idea represents the real number of sheep present in the flock. The correspondence of the idea with the facts constitutes that to which the assertion is committed. If the correspondence exists, the assertion is true.

Such being (according to the 'correspondence' theory) the nature of truth, error takes place when, because of inadequate observation of the sheep, or because of some other psychological defect on the part of the one who counts, a numerical idea which does not correspond to the real number of the

sheep arises in the mind that is subject to the error; while, because of these or of still other psychological motives, the false proposition 'Such is the number of sheep,' comes to be asserted. That the correspondence does not exist makes the proposition false. That this non-existent correspondence is asserted and believed to exist constitutes the essence of the error.

In order to understand what error is, and how it arises, one therefore needs, according to this view, to analyze the nature of belief, and the motives which lead the erring mind to make assertions. From this point onwards, the definition and the theory of error have always required the consideration of various associative, affective, or volitional factors of the process of making and believing assertions – factors of which pure logic considered in its usual abstraction, can give no account. In brief, the nature of truth and falsity once having been thus defined, the nature of error depends upon some disposition to accept or to assert an untrue proposition – a disposition which cannot be due to the merely logical nature of the untruth itself, but must be referred to the prejudices, the feelings, the ignorance, the wilfulness, or the other psychological fortunes of the erring subject.

What further accounts, upon this basis, have been attempted as explanations of the essence of error, there is here no space to set forth at length. A few points must be noted. One may assert: (1) that error in such a case as the foregoing, or in the more complex cases of superstitions, supposed theological heresies, false philosophies, errors in scientific opinion, false political doctrines, etc., may be mainly due to a negative cause – the mere ignorance of the erring subject, his lack of 'adequate ideas,' the absence of correct and sufficient portrayals of fact. What a man lacks he cannot use. If he has no ideas that correspond with the facts in question, how can he make true assertions? Error is then, at least in the main (according to the view now in question), due to privation. For instance, I may not even attempt to count the sheep in the flock. I may merely guess at random. In such a case, error seems to be due merely, or mainly, to my lack of ideas. Such a negative theory of error was worked out by Spinoza, and applied by him, as far as possible, to decidedly complex cases. Naturally, according to Spinoza, 'the order and connexion of ideas' corresponds to 'the order and connexion of things.' This, for Spinoza, is the case with even the most worthless of our human imaginations. But for psycho-physical reasons, which Spinoza discusses at length, most ideas of the ordinary man, relating to his world, are extremely 'inadequate'; that is, such ideas correspond only to very fragmentary aspects of the real world. The majority of men live 'ignorant of God and of themselves and of things.' This ignorance prevents them from possessing the stock of ideas which could furnish the basis for true opinions. Men fill the void with errors. Yet none even of their errors is without basis in fact. They simply judge, without restraint, concerning that of which they know not, just because they know so little. This doctrine of error as ignorance, if accepted, would give us the

most purely and completely theoretical definition of error which has ever been offered.

Plainly, however, ignorance is not of itself error. I cannot err concerning facts of which I know so little as to have no idea whatever about them; just as I cannot, in a speech, make grammatical blunders of whose existence I have never heard. Some other factor than ignorance determines the actual acceptance and utterance of false propositions. This even Spinoza himself has in the end to recognize. In his study of the errors of human passion, he makes the mechanical associative process, and the resulting passions themselves, factors in the genesis of error. Thus we are inevitably led to further theories.

One may assert: (2) that error is due to whatever moves the will of the erring subject to make the assertions even in the absence of ideas that correspond to real objects. This volitional theory of error played a considerable part in Scholastic doctrine; was obviously useful in giving reasons for the moral condemnation of the errors of heretics, infidels, and schismatics; and has, in fact, an obvious and important basis in the psychology of opinion. Descartes recognized it in connexion with his own form of the doctrine of the freedom of the will. Spinoza, who rejected the theory of free will, and defined both intellect and will in terms of his psycho-physical theory of the associative process, still on occasion was obliged, as just pointed out, to use his own version of the doctrine of 'human bondage' as an explanation of the fatal errors into which the play of our inadequate ideas and of our passions leads us. In other forms this theory of error is widely accepted. From this point of view an error is a wilful assertion of a false proposition – an assertion made possible, indeed, by the erring subject's ignorance of the ideas that do correspond with reality, but positively determined by his willingness to assert. False beliefs are thus due to a combination of ignorance with the will to believe.

One may insist (3) that the affective processes which condition the mood called 'belief' are the principal factors in making a false proposition, when it chances to be suggested, seem plausible. Where error is propagated by social contagion, or is accepted through reverence for authority, not so much the will as the emotional life of the erring subject seems to be the factor which makes error possible. Here, according to the previous view, ignorance of ideas that do correspond with reality is a condition of error, but constitutes neither its essence nor its sufficient cause. An error, according to the present view, is a false opinion which, because of its appeal to the sentiments, the feelings, the prejudices, of the erring subject, because it is harmonious with his social interests or with his private concerns, wins the subject over to the state of mind called belief.

One may further maintain: (4) that the principal cause of error is whatever associative, perceptual, or imaginative process gives such liveliness, strength, and persistence to ideas which as a fact do not correspond with reality, that the erring subject is forced, in the absence of sufficient corrective ideas, or (to

use Taine's expression) for lack of 'reductors,' to regard these ideas as representatives of reality. Theories of error founded upon this view have played no small part in the psychiatrical literature which deals with the genesis of pathological forms of error, and have been prominent in the teachings of the Associationist school generally. From this point of view, an error is a false proposition whose assertion is forced upon the erring subject through the mechanism of association, and mainly because no other ideas than those which this assertion declares to correspond with the facts can win a place in the subject's mind when he thinks of the topic in question.

The foregoing accounts of the nature and source of error have all been stated with explicit reference to the 'correspondence' theory of truth. This theory supposes that the test of truth is the actual conformity of a representative idea with the object which it is required to portray. Idea and object are viewed as distinct and separable facts, just as a man and his portrait or photograph are possessed of a separate existence. The representative idea is external to the object. Truth depends upon a certain agreement between such mutually external facts. And, just as the idea to whose truthfulness as a representation a proposition is committed is external to its object, so, as we have now seen, the motives which lead us to error appear, in the accounts thus far given, to be external to the meaning, and to the truth or falsity, of ideas and propositions. The falsity of a proposition, so far as we have yet seen, gives no reason why the error involved in believing that proposition should be committed. The truth of a proposition, also, in no wise explains why the true proposition comes to be believed – unless, indeed, with Spinoza, one comes to accept, for metaphysical reasons, a theory that ideas are by nature in agreement with objects. In case, however, one does accept the latter theory without any limitation, then error can be defined only in negative terms as due to mere absence of ideas. Such an account of error, as we have also seen, is incapable of telling us what it is, and is inadequate to explain the most familiar facts about its occurrence.

If, then, the truth or the falsity of a proposition does not of itself explain why we come to get a true or false belief, the existence of error, for one who accepts the correspondence theory of truth has to be explained by psychological motives which are as external to the logical meanings of true and false propositions as the ideas of the correspondence theory of truth are external to their objects. Some propositions are true. Their contradictories are false. So far, we have a system of facts and relations that seems according to this account, to be wholly independent of the psychological processes of anybody. But of these true and false propositions, some are believed by men. If the propositions believed are true, we have not explicitly considered in the foregoing the psychology of the process by which they come to be believed. But, if the beliefs are beliefs in false propositions, some accounts of how the errors arise have been suggested. These accounts all appeal to motives which

do not result from the falsity of the propositions, but from the feelings, the will, or the associative processes of the erring subject – all of them influences which are due not to the logical distinctions between true and false, but to the mental fortunes of the believer.

Unfortunately, however, since the true beliefs of the subject must also have their psychology, quite as much as the false beliefs, and since the will, the feelings, the associative processes, the conditions which determine 'lively ideas,' and the like, must be equally effective when true propositions are believed as when false beliefs triumph – all the foregoing accounts leave us dissatisfied should we be led to ask: What are the processes which prevent error and give us true beliefs? For, apart from Spinoza's assumption of the universal agreement between 'the order and connexion of ideas and the order and connexion of things' – an assumption which makes error in any but a purely negative sense impossible – the truth of a proposition is a fact which in no wise explains why we mortals should come to believe that proposition to be true. And, if we explain the true belief as due to the will, the feelings, the associative or other psychological processes of the subject, these factors, as the theories of error so far stated have insisted, work as well to produce error as to beget true opinion. The one thing of which we have so far given no account is the way in which the difference between true opinion and error arises – the factor which is decisive in determining whether a given state of opinion, in a given subject, shall be one which accepts true propositions or, on the contrary, embraces error.

Of course, the need of such an account has frequently been felt by the partisans of the 'correspondence' theory of truth. Innumerable portrayals exist of the ways in which conformity of idea and object can be furthered or attained by psychological processes. Ideas can be made 'clear and distinct,' observations of the object can be rendered careful, prejudice can be kept in abeyance, feeling can be controlled, judgment can be suspended until the evidence is incontestable, and so on. By such means error can be more or less completely avoided, and agreement with the object can be progressively obtained. There is no doubt of the practical importance of such advice. There is also no doubt that the processes of control and of clarification which are in question are psychological processes, which the inquiring subject can find or produce within himself. It becomes plain, however, as one reflects, that to insist upon such matters is more or less to modify, and in the end to abandon, the representative theory of truth as consisting merely in the conformity of ideas to objects that are external to these ideas.

For how does one know, or why does one judge, that clear ideas, careful observations, the avoidance of prejudice, the suspension of judgment, and the other psychological devices of the truth-seeker, actually tend to make the subject escape from error, and win true opinion? Is it because, from some point of view external both to the object and to the ideas of the subject, one

observes how the subject gradually wins a closer conformity with his object through using the better devices, and through avoiding the mental sources of error? If so, then whoever has this point of view, external both to the object and to the cognitive process, is already somehow acquainted with the constitution of the object, and is aware what propositions are true about the object quite apart from the psychological fortunes of the poor subject, whose escape from error is to be aided by such wise counsels. As a fact, philosophers who give such counsels very often behave for the moment as if they, at least, had not to wait for a slowly acquired conformity with the nature of reality, but were already assured of their own grasp of the object, and were therefore able to give such good advice to the erring psychological subject. No purely psychological theory of the way in which a conformity to an external object can be gradually acquired through clear ideas, freedom from prejudices, and so on, can serve to explain how the critic of human truth and error has himself acquired his assumed power to see things as they are, and thus to guide the psychological subject in the right path. That sort of attainment of truth which this theory attributes to the philosopher who teaches it is just what it does not explain.

In fact, a little reflexion shows that, when we hold, as we very rightly do, that a certain wise conduct of our ideas, feelings, will, observations, processes of recording observations, and other such mental enterprises helps us towards truth, and aids us to avoid error, we are comparing, not ideas with merely external objects, so much as less coherent with more coherent, unified, clear, and far-reaching forms of experience, of cognition – in general, of insight. If we once see this fact, we have to alter our definition of truth, and herewith our definitions both of true opinion and of error.

Truth cannot mean mere conformity of idea to external object; first, because nobody can judge an idea merely by asking whether it agrees with this or with that indifferent fact, but only by asking whether it agrees with that with which the knowing subject meant or intended it to agree; secondly, because nobody can look down, as from without, upon a world of wholly external objects on the one hand, and of his ideas upon the other, and estimate, as an indifferent spectator, their agreement; and thirdly, because the cognitive process, as itself a part of life, is essentially an effort to give to life unity, self-possession, insight into its own affairs, control of its own enterprises – in a word, wholeness. Cognition does not intend merely to represent its object, but to attain, to possess, and to come into a living unity with it.

Accordingly, the theories of error which have been founded upon the 'correspondence' theory of truth must be, not simply abandoned, but modified, in the light of a richer theory of truth. A true proposition does, indeed, express a correspondence between idea and object, but it expresses much more than this.

(ii.) Another definition of truth, which has its foundation far back in the history of thought, but which has been of late revised and popularized under the names of Pragmatism, Humanism, and Instrumentalism, may next be mentioned.

According to this view, an idea is essentially something that tends to guide or to plan a mode of action. A proposition expresses the acceptance of such a mode of action, as suited to some more or less sharply defined end. Now, a mode of action inevitably leads to consequences, which arise in the experience of the active subject. These consequences may be called the 'workings' of that idea which tended to guide or to plan this mode of action. These workings may agree or disagree with the intent of the idea. If the idea agrees with its expected workings, that idea is true, and with it the proposition which accepts that idea as suited to its own ends is true; otherwise the idea and the proposition are erroneous. Such is the definition of truth which is characteristic of Pragmatism.

The case of the right or wrong counting of the flock of sheep will serve to illustrate the present theory of true opinion and of error quite as readily as to exemplify the representative theory of the same matters. A flock of sheep is not merely an external object to be portrayed. It is, to the one who counts it, an interesting object of human experience. He counts it in order to be ready to estimate his possessions, to sell or to buy the flock, to know whether he needs to hunt for lost sheep, or because of some other concrete purpose. His counting gives him an idea, perhaps of what he ought to ask of a purchaser, or of a plan for the shearing or for the market, perhaps of whether he ought to search for missing sheep. When he accepts and asserts that some determinate number represents the actual number of the flock, he, no doubt, takes interest in the correspondence between the idea and the object; yet his real object is not the indifferent external fact, but the flock of sheep as related to his own plans of action and to the practical results of these plans. The only test of the truth of his count, and, in fact, the only test that, when he counts, he proposes to accept, is that furnished by the workings of his count. Does his idea of the number of the sheep, when accepted, lead to the expected results? One of these results, in many cases, is the agreement of his own count with that made by somebody else, with whom he wishes to agree concerning a sale or some other enterprise. Or, again, he expects the enumeration which he makes at one time to agree with the result obtained at some other time when he counts the flocks anew. Furthermore, a habit of inaccurate counting betrays itself, in the long run of business, in the form of failure to get expected profits, or in the form of a loss of sheep whose straying is at one time not noticed because of inaccurate counting; while later experience shows, in the form of the experience which traces the loss, the non-correspondence of expectations and results. Such expectations, tests, and agreements define the sort of truth that is sought.

What so simple and commonplace an instance illustrates, the whole work of the natural sciences, according to the pragmatist, everywhere exemplifies. The Newtonian theory of gravitation is accepted as true because its ideas lead, through computations, to workings which agree with observation. The corpuscular theory of light was rejected because certain of its consequences did not agree with experience. The same process of testing hypotheses by a comparison of expectations with outcome can be traced throughout the entire range of empirical investigation.

As to the cause and essence of error, upon the basis of this theory of truth, there can be, according to the pragmatist, no very subtle difficulties to solve. The whole matter is, upon one side, empirical; upon the other side, practical. Experience runs its course, however it does. We, the truthseekers, are endeavouring to adjust our actions to empirical happenings by adapting our expectations, through the definition of our ideas, and through the forming and testing of our hypotheses, to the observed facts as they come. As we are always in our practical life looking to the future, and are seeking the guidance which we need for our undertakings, our propositions are hypotheses to the effect that certain ideas will, if tested, agree with certain expected workings. If the test shows that we succeed, then, just when and in so far as we succeed, our propositions prove to be then and there true. If we fail, they prove to be errors. Truth and falsity, and, consequently, true opinion and error, are not 'static' properties or fixed classifications of our ideas or of our hypotheses. Both the ideas and the propositions 'come true' or 'fail to come true' through the fluent and dynamic process of the empirical test. Thus every truth is true and every falsity false, relatively to the time when, and the purpose for which, the individual idea or hypothesis is tested.

Absolute truth or permanent truth, and equally absolute falsity or permanent falsity, are from this point of view, purely abstract and ideal predicates, useful sometimes for formal purposes when we choose to define our purposes in terms of logical or of mathematical definitions. 'Concrete' truth and error are of the nature of events, or series of events, or of 'the long run' of experience. That many of our ideas should not 'work,' or that many of our hypotheses should result in disappointed expectation is, for the pragmatist, merely an empirical fact, requiring a special explanation no more than do the marksman's missing or the player's failure to score. We are not perfectly skillful beings; experience is often too fluent or too novel for our expectations. The wonder is rather that this is not more frequently the case. That man is as skillful a player as he is of the game of ideal expectations and anticipated consequences is a matter for congratulation. But failure is as natural an event as is success.

The traditional accounts of the psychology of error mentioned above are readily accepted by Pragmatism, precisely in so far as they are indeed accounts which experience justifies. No doubt, ignorance is a source of error. We are,

in fact, ignorant of all except what experience, in one way or another, permits us upon occasion to prove by actual trial. This ignorance permits errors, in the form of false expectations, to arise. Prejudice, emotion, wilfullness, and the associative process unite to engender expectations which may prove to be false. Nor is there any known cause that uniformly assures the attainment of truth. The difference between success and failure in our adjustment to our situation is simply an empirical difference. We have to accept it as such. No deeper account can be given than experience warrants.

The result of the pragmatist's definition of error obviously forbids any sharp distinction between theoretical and practical errors. The presence or absence of conscious ideas, of definite expectations, of articulate hypotheses, remains (in case of our always more or less practically significant maladjustments of our acts to our situation) as the sole criterion for distinguishing between erroneous opinions, on the one hand, and blunders that are made, on the other hand – merely as the fumbling player may fail to get the ball, or as the nervous musician may strike the false note – blindly, and without knowing why one fails, or what false idea, if any, guided one to the failure. This reduction of all errors to the type of practical maladjustments is a characteristic feature of Pragmatism.

If the 'correspondence' theory of truth makes the distinction between true and false opinions something that is quite external to the logical distinction between true and false propositions, the pragmatist's theory of truth and error in propositions seems, on the contrary, to go as far as is possible to annul altogether the difference between these two sorts of distinctions. For the pragmatist it is merely a formal device of the logician to regard truth and error as in any sense permanent properties, or predicates of the supposed entities called propositions. What actually occurs, what empirically happens, is a series of concrete agreements and disagreements between expectations and results. These happenings or 'the long run' of such happenings, constitute all that is concretely meant by truth and error. Whether one says, 'This proposition is true or false' or 'This opinion is true or false,' the concrete fact to which one refers is the sequence of testings to which ideas are submitted when their expected workings are compared with the expectations. Since logicians like to abstract certain 'forms' from the matter of life, they may, if they choose, define the entities called true and false propositions, and then leave to the students of the concrete the study of the fortunes of mere opinions. As a fact, however, according to Pragmatism, propositions live only as opinions in process of being tested. The distinctions with which we began this discussion have their own provisional usefulness, but only as abstractions that help to prepare the way for understanding life. A proposition becomes true in the concrete when the opinion that is true leads to expected workings, and becomes false when the belief in it leads to workings which do not agree with expectations.

Such, in sum, is the pragmatist's solution of our initial problem. It emphasizes very notable facts regarding the relations between logic and life, and between thought and volition. Yet it fails to satisfy. For it can only be stated by constantly presupposing certain assertions about experience, about the order, the inter-relations, the significance, and the unity of empirical facts to be true, although their truth is never tested, in the pragmatist's sense of an empirical test, at any moment of our experience.

Thus, it has been necessary to assume, even in stating the view of Pragmatism about truth, that ideas can be formed at one time, and submitted to the test of experience at another time, and perhaps by another person, just as Newton's hypotheses were formed by him, but were tested, not only by himself, through a long course of years, but by later generations of observers. It has been necessary to assume that one can form expectations today, and compare them with facts to-morrow, or next year, or after whatever length of time the conditions make possible. But this assumption requires the truth of the proposition that the meaning, the object, the purpose, the definition of the ideas, and expectations of one moment or period of time, or person, not only can be but are identical with the meaning, object, purpose, definition of the ideas and expectations of another moment, temporal region, or person. Now such an assertion, in any one case, may be regarded with scepticism, since it is, for human beings, unverifiable. Nobody experiences, in his own person or at any one time, the identity of the ideas, meanings, expectations, of yesterday and today, of himself and of another person, of Newton and of the later students of Nature who have tested what they believe to be Newton's ideas. One may, in each special case, doubt, therefore, whether the idea formed yesterday is the same in meaning as the idea tested today, whether two men mean the same by the hypotheses which they are trying to verify together, and so on. But this much seems clear: however doubtful, in the single case, any such proposition may appear, unless some such propositions are true, there is no such process as the repeated testing of the same ideas through successive processes of experience, occurring at separate moments of time, or in the experiences of various human observers. But in that case it is not true that the proposition, 'Such a testing of ideas by the course of experience as Pragmatism presupposes actually takes place,' expresses the facts. If, however, this proposition is not true, the whole pragmatist account of truth becomes simply meaningless. On the other hand, if the proposition is true, then there is a kind of truth whose nature is inexpressible in terms of the pragmatist's definition of truth. For there are propositions which no human being at any moment of his own experience can ever test, and which are nevertheless true.

Much the same may be said of the pragmatist's assertion regarding the 'workings' that an idea is said to 'possess' or to which it is said to 'lead.' These 'workings' by hypothesis, may extend over long periods of time, may find a place in diverse minds, and may involve extremely complex reasoning

processes (e.g., computations, as in the case of the Newtonian theory of gravitation) which are very hard to follow, and which no human mind can survey, in their wholeness, at any moment, or submit to the test of any direct synthetic observation. The proposition, however, 'These are the actual, and, for the purposes of a given test, the logically relevant workings of the idea that is to be tested,' must itself be true, if the empirical comparison of any one of these workings with the facts of experience is to be of any worth as a test. The truth of the proposition just put in quotation marks is a truth of a type that no one man, at any instant, ever personally and empirically tests. In every special case it may be, and in general must be, regarded as doubtful. Yet, unless some such propositions are true, Pragmatism becomes a meaningless doctrine; while, if any such propositions are true, there is a sort of truth of which Pragmatism gives no account.

What holds of truth holds here, in general, of the conditions which make falsity possible. And the whole theory of true and false opinion, and consequently the definition of error, must be modified accordingly. In brief, Pragmatism presupposes a certain unity in the meaning and coherence of experience taken as a whole – a unity which can never at any one moment be tested by any human being. Unless the propositions which assert the existence and describe the nature of this presupposed unity are themselves true, Pragmatism has no meaning. But, if they are true, Pragmatism presupposes a sort of truth whereof it gives no adequate account. To say this is not to say that Pragmatism gives a wholly false view of the nature of truth, but is only to insist upon its inadequacy. It needs to be supplemented.

(iii.) Over against the theory of truth as the correspondence between a wholly external object and an ideal portrayal, and also in contrast with Pragmatism, there exists a theory of truth which defines that concept wholly in terms of a harmony between the partial expression of a meaning which a proposition signifies and the whole of life, of experience, or of meaning, which, according to this theory, ideas and propositions intend to embody so far as they can. A proposition is true in so far as it conforms to the meaning of the whole of experience. Such conformity can never be attained through the mere correspondence of a portrayal with an external object. It can exist only in the form of the harmonious adaptation of part to whole – an adaptation that can best be figured in the form of the adaptation of an organ to the whole of an organism.

If one reverts to the comparatively trivial instance of the sheep and the counting, the present view would insist, as Pragmatism does, upon the fact that, in counting sheep, one is attempting to adjust present ideas to the unity of an extended realm of experience, in which the observed sheep appear, now as grazing in the field, now as having their place in the herdsman's enterprises, now as passing from one ownership to another, and so on. The one who counts wants to get such a present idea of the sheep as will stand in harmo-

nious unity with all else that can be or that is known with regard to them. The truth involved in the process of counting is itself of a relatively abstract and lower sort; and hence is ill adapted to show what truth really is. For, in fact, to treat sheep merely as numerable objects is to treat them as what, on the whole, they are not; hence to say, 'They are so many,' is to utter what is in some respects false. For they are sheep, and to say this is say that each is a living organism, a unique individual, a product of ages of evolution, and a being possessing values beyond those which commerce recognizes. Hence a numerical account of them has only 'partial truth,' and therefore is false as well as true. The only wholly true account of the sheep would express (not merely portray) their character as facts in the universe of experience and of reality. One can say, at best, of the proposition about their number that it is true in so far as it expresses a view about them, which harmonizes, to the greatest extent possible for a numerical statement, with what experience, viewed as a whole, determines the place and the meaning of one's present experience of the flock of sheep to be.

Truth from this point of view is an attribute which belongs to propositions in a greater or less degree. For single propositions, taken by themselves, give us abstract accounts of facts, or rather of the whole in which every fact has its place, and from which it derives its characters. A proposition is an interpretation of the whole universe, in terms of such a partial experience of the nature of the whole as a limited group of ideas can suggest. This interpretation is always one-sided, precisely in so far as the group of ideas in question is limited. In so far as the partial view harmonizes with the whole, the proposition is true. Since the partial view, being one-sided, can never wholly harmonize with the whole, each separate proposition, if taken in its abstraction, is partially false, and needs to be amended by adding other propositions.

This general theory of truth and falsity, while its sources run back into ancient thought, is especially characteristic of modern Idealism. That the truth of propositions about experience is a character determined by their relation to the ideal and virtual whole of experience, to the 'unity of apperception,' is a thesis which forms part of Kant's 'Deduction of the Categories.' The later developments of the 'Dialectical Method,' by Fichte and Hegel, and the analogous features of Schelling's thought, led to more explicit theories of the relations between truth and falsity, and to the doctrine that every proposition, considered in its abstraction, is partially false, and needs amendment. Hegel, in the preface to his *Phänomenologie*, asserted that 'Das Wahre ist das Ganze,' and interpreted this as meaning that only what a survey of the total process of experience signifies enables us to know truth, while 'partial views,' such as we get on the way towards *absolutes Wissen*, are at once true and false – true as necessary stages on the way to insight, and therefore as in harmony with the purposes of the whole; false, as needing supplement, and as showing

this need through the contradictions which give rise to the dialectical process. In Hegel's *Logic* this view of truth is technically developed. With a different course of argument, with many original features, and with a more empirical method of investigation, a view of truth and error which belongs to the same general type has in recent times been developed by Bradley.

If one accepts such a theory of the 'degrees of truth and falsity,' and of truth as the harmony or organic unity between a partial view and the ideal whole of experience or of reality, the essence of error – that is, of false opinion must receive a new interpretation. In the history of the development of Absolute Idealism, the theory of error has taken, on the whole, two distinct forms.

(1) According to the first of these forms, usually emphasized by Hegel, error exists merely because it is of the essence of partial view to regard itself as the total and final view, precisely in so far as the partial view inevitably passes through the stage of 'abstraction,' in which it defines itself to the exclusion of all other points of view than its own. Did it not pass through this stage, it would not be a live or concrete view of things at all. It simply would not exist. But (according to Hegel) the whole, in order to be an organism at all, requires the parts to exist. And, if the parts are – as in the case of opinions – partial views of the whole, and if the whole requires them to exist, each in its place in the system of spiritual life, it is the whole itself, it is the Absolute, which requires the partial view to make, as it were, the experiment of regarding itself as true – that is, as an absolutely whole view. If a man is merely counting, he takes his objects simply as numerical; and then real things seem to him, as to the Pythagoreans, to be merely 'numbers.' Such a view, as an abstraction, is false; but as a stage on the way to insight it is inevitable; and as a concrete phase of opinion it is an error, that is, a positive belief in a falsity, or, again, a taking of a partial view for the whole. To be sure, this 'dwelling on the abstraction,' this *beharren* or *verweilen* in the midst of falsity, is a phase; and since, for Hegel (just as much as for the Pragmatists), the apprehension of truth is a living process, not a static contemplation, this phase must pass. An experience of the 'contradictions of finitude' must in its due time arise, and must lead to the recognition that the partial phase is false. This is what happens in the course of the history of thought, when the successive systems of philosophy – each a partial truth, required by the necessity of the thought-process and by the life of the *Weltgeist* to regard itself as absolutely true – succeed one another with a dialectical necessity that tends to larger and truer insight. The same sequence of necessary errors, which are all of them partial truths taking themselves to be whole and final, appears in the history of religion.

(2) To Bradley, and to others among the more recent representatives of Idealism, to whom the dialectical method of Hegel appears in various ways unsatisfactory, this account of the way in which error arises, and, as a phase of experience and of life, is necessary, does not appeal. For such thinkers,

error is, indeed defined as a partial and (in so far) false view, which is not merely partially false and partially true, but takes itself to be wholly true. The existence of such a disharmony between part and whole, in a realm of experience where the metaphysical presuppositions which these writers accept seem to require organic wholeness and harmony to prevail, and to be of the essence of reality, is an inexplicable event, which must be viewed as in some unknown way a necessary 'appearance,' not a reality.

As a statement of the ideal of truth which is alone consistent with rational demands, the Idealism thus summarized seems to be, in great measure, successful. But its success is greatest with respect to the conception of truth as the teleological harmony or adjustment of a partial to a total view of experience and of its meaning. Precisely with regard to the problem of the possibility of error, that is, of disharmony between the demands of any partial interpretation of experience and that which is revealed and fulfilled by the whole of experience, the idealistic theory of truth and of error has proved to be, thus far, most incomplete.

4. *Conditions of a solution of the problem of error.* The foregoing survey shows that a satisfactory theory of error must meet the following requirements:

(1) It must be just to whatever interest in a decisive and unquestionably 'absolute' distinction between true propositions and their contradictory false propositions is justly urged by formal logic. That is, no account of truth and error in terms of 'partial views' and 'the total view' of experience must be used to render the contrast of true and false anything but a decisive contrast, as sharp as that between any proposition and its contradictory.

(2) The theory of error must take account of the actual unity of the cognitive and volitional processes. It has been the office of recent Pragmatism to insist, in its own way, upon this unity. But Hegel, in his *Phänomenologie*, also insisted, although in another fashion, upon the fact that every insight or opinion is both theoretical and practical, is an effort at adjustment to the purposes of life, an effort to be tested by its genuine rational success or failure.

(3) The theory of error must recognize that truth is a character which belongs to propositions so far as they express the meanings which our ideas get in their relations to experience, and not in their relations to wholly external objects.

(4) That the rational test or the success of ideas, hypotheses, and opinions lies in their relations not to momentary experiences, but to the whole of life, so far as that whole is accessible, must also be maintained.

(5) The existence of error, as disharmony between the partial view which actively and, so to speak, wilfully asserts itself as the expression of the whole, must be explained as due to the same conditions as those which make possible finite life, evil, individuality, and conflict in general.

(6) Theoretical error cannot be separated from practical error.

(7) A revision of Hegel's dialectical method, a synthesis of this method with the empirical tendencies of recent Pragmatism, a combination of both with the methods of modern Logic seem, in their combination, to be required for a complete treatment of the problem of error. An error is the expression, through voluntary action, of a belief. In case of an error, a being, whose ideas have a limited scope, so interprets those ideas as to bring himself into conflict with a larger life to which he himself belongs. This life is one of experience and of action. Its whole nature determines what the erring subject, at his stage of experience, and with his ideas, ought to think and to do. He errs when he so feels, believes, acts, interprets, as to be in positive and decisive conflict with this *ought*. The conflict is at once theoretical and practical.

THE WORLD AND THE WILL

Josiah Royce. "The World and the Will." *Sources of Religious Insight* (Edinburgh: T.&T. Clark, 1912), chap. 4, sections IV–VII, pp. 135–161.

IV

Our illustrations have now prepared the way for a general review of the relations between our reason and our will. We are ready at length to ask whether any insight of reason, whether any general view of the nature and of the unity of the world or of life, could possibly be a merely theoretical insight. And if we rightly answer this question, we shall be prepared to reply to the objection that, according to the doctrine of the last lecture, the divine insight which overarches our ignorance, and which has all reality for its object, is a lifeless, or an unpractical, or a merely remote type of pure knowledge.

Our attempt to deal with this new question can best be made by taking a direct advantage of what some of you may suppose to be the most formidable of all objections to the whole argument of the last lecture. In my sketch of a philosophy of the reason, I have so far deliberately avoided mentioning what many of you will have had in mind as you have listened to me, namely, that doctrine about our knowledge, and about truth, and about our mode of access to truth, which to-day goes by the name of Pragmatism. Here we have to do, once more, with some of the favorite theses of James's later years. We have also to do with a view with which my present audience is likely to be familiar, at least so far as concerns both the name pragmatism and the best-known fundamental theses of the pragmatist. For I speak in the immediate neighborhood of one of the most famous strongholds of the recent pragmatic movement. I can give but a comparatively small portion of our limited time to the task of explaining to you how I view those aspects of pragmatism which here concern our enterprise. Yet this summary discussion will go far, I hope, to show how I view the relations between the reason and the will, and in how far our will also seems to me to be a source of religious insight.

That human knowledge is confined to the range furnished by human experience, and cannot be used to transcend that experience, is an opinion widely represented in all modern discussion, and especially in the most recent times. My own account of the insight which I refer to the reason depends not upon simply ignoring this general doctrine about the limitations of our human knowledge, but upon an effort to get a rational view of what it is that

we mean by human experience. My result, as I have stated it, may have seemed paradoxical; and I am far from supposing that my brief sketch could remove this paradoxical seeming, or could answer all objections. My thesis is essentially this, that you cannot rationally conceive what human experience is, and means, except by regarding it as the fragment of an experience that is infinitely richer than ours, and that possesses a world-embracing unity and completeness of constitution. My argument for this thesis has been dependent on an assertion about the sense in which any opinion whatever can be either true or false, and upon a doctrine regarding that insight to which we appeal whenever we make any significant assertion.

Now this argument will seem to some of you to have been wholly set aside by that account of the nature of judgments, of assertions, and of their truth or falsity, which pragmatism has recently maintained. A new definition of truth, you will say – or, an old definition revived and revised; a new clearness also as to the ancient issues of philosophy; an equally novel recent assimilation of philosophical methods to those that have long been prominent in natural science – these things have combined, at the present moment, to render the Platonic tradition in philosophy and the laborious deductions of Kant, as well as the speculations of the post-Kantian idealists, no longer interesting. I ought, you may insist, to have taken note of this fact before presenting my now antiquated version of the idealistic doctrine of the reason. I ought to have considered fairly the pragmatist's theory of truth. I should then have seen that our human experience may safely be left and must rationally be left, to fight its own way to salvation without any aid from the idea of a universal or all-embracing or divine insight.

How does pragmatism view the very problem about the truth and error of our human opinions which has led me to such far-reaching consequences? For the first, it is the boast of pragmatists that they deal, by preference, with what they call "concrete situations," and our "concrete situation" as human beings dealing with reality is, as they maintain, something much more readily comprehensible than is the idealistic theory of a divine insight. Truth and error are characters that belong to our assertions for reasons which need no overarching heavenly insight to make them clear. In brief, as the pragmatists tell us, the story of the nature of truth and of error is this:

An assertion, a judgment, is always an active attitude of a man, whereby, at the moment when he makes this assertion he directs the course of his further activities. To say "My best way out of the woods lies in that direction" is, for a wanderer lost in the forest, simply to point out a rule or plan of action and to expect certain results from following out that plan. This illustration of the man in the woods is due to James. An analogous principle, according to pragmatism, holds for any assertion. To judge is to expect some concrete consequence to follow from some form of activity. An assertion has meaning only in so far as it refers to some object that can be defined in empirical terms

and that can be subjected to further direct or indirect tests, whereby its relations to our own activities can become determinate. Thus, then, a judgment, an opinion, if it means anything concrete, is always an appeal to more or less accessible human experience – and is not, as I have been asserting, an appeal to an overarching higher insight. When you make any significant assertion, you appeal to whatever concrete human observations, experiments, or other findings of data, actual or possible, can furnish the test that the opinion calls for. If I assert: "It will rain to-morrow," the assertion is to be verified or refuted by the experience of men just as they live, from moment to moment.

It remains to define, a little more precisely, wherein consists this empirical verification or refutation for which a human opinion calls. An opinion is a definite one, as has just been said, because it guides the will of the person who holds the opinion to some definite course of action. An opinion then, if sincere and significant, has *consequences*, leads to deeds, modifies conduct, and is thus the source of the experiences which one gets as a result of holding that opinion and of acting upon it. In brief, an opinion has what the pragmatists love to call its "*workings*." Now when the workings of a given opinion, the empirical results to which, through our actions, it leads, agree with the expectations of the one who holds the opinion, the opinion is to be called true. Or, in the now well-known phrase, "An idea (or opinion) is true if it works." To use the repeated example of Professor Moore, an opinion that a certain toothache is due to a condition present in a given tooth is true, when an operation performed upon that tooth, and performed as a consequence of that opinion, and with the expectation of curing the toothache works as expected. For the operation is itself one of the workings of the opinion in question.

To assert an opinion, then, is not to appeal to an essentially superior insight, but is to appeal to the workings that follow from this opinion when you act upon it in concrete life. No other sort of truth is knowable.

A consequence of these views, often insisted upon by pragmatists, is that truth is relative to the various "concrete situations" which arise; so that absolute or final truth is indefinable by us mortals. Hence an opinion may be true for a given purpose, or in one situation (because in that situation its workings prove to be as expected), although it is relatively false when applied to some other situation, or to some wider range of experience. Absolute truth is as unobservable by us in our experience as is absolute position or absolute motion in the physical world. Every truth is definable with reference to somebody's intentions, actions, and successes or failures. These things change from person to person, from time to time, from plan to plan. What is true from the point of view of my plans need not be so from your point of view. The workings of an opinion vary in their significance with the expectations of those concerned. Truth absolute is at best a mere ideal, which for us throws no light upon the nature of the real world.

Thus, at a stroke, pragmatism, as understood by its chief representatives at the present time, is supposed to make naught of the subtle, and, as the pragmatists say, airy and fantastic considerations upon which my sketch of a philosophical idealism at the last lecture depended. Truth, they insist, is a perfectly human and for us mortals not in the least a supernatural affair. We test it as we can, by following the experienced workings to which our ideas lead. If these workings are what we meant them to be, our opinions are just in so far proven true. If no human and empirical tests of the workings of an opinion are accessible to us, the opinion remains in so far meaningless. If concrete tests lead to workings that disappoint our human expectations, our opinions are in so far false. Moreover (and upon this all the pragmatists lay great stress), truth is for us a temporal affair. It changes, it flows, it grows, it decays. It can be made eternal only by tying ourselves, for a given purpose, to abstract ideas which we arbitrarily require to remain, like mathematical definitions, unchanged. Even such ideas have no sense apart from the uses to which they can be put. Concrete truth grows or diminishes as our successes in controlling our experience, through acting upon our beliefs, wax or wane.. Truth is subject to all the processes of the evolution of our concrete lives. The eternal is nothing that can be for us a live presence. What we deal with is, like ourselves, fluent, subject to growth and decay, dynamic, and never static. The pragmatist recoils with a certain mixture of horror and amusement from the conception of an all-inclusive divine insight. That, he says, would be something static. Its world of absolute reality would be a "block universe" and itself merely an aspect of a part, or perhaps the whole, of just this block. Its supposed truth would be static like itself, and therefore dead.

But does pragmatism forbid us to have religious insight? No; James, in ways which you have repeatedly heard me mention, insists that pragmatism leaves open ample room for what he thinks to be the best sort of religion, namely, for a religion suited to what he calls the "dramatic temper" of mind. Truth, so far as we men can attain to it, has indeed to be human enough. But nothing forbids us to entertain the belief that there are superhuman and supernatural realities, forms of being, living and spiritual personalities, or super personalities, as various and lofty as you please, provided only that they be such as to make whatever evidence of their being is accessible to us capable of definition in a human and empirical way. The truth, namely, of our belief about such beings, has to be tested by us in terms of our own concrete religious experience. Such beliefs, like others, must "work" in order to be true. That is, these beliefs, however they arise, must lead to conduct; and the results of this conduct must tend to our religious comfort, to our unity of feeling, to our peace, or power, or saintliness, or other form of spiritual perfection. The fruits of the spirit are the empirical tests of a religious doctrine; and, apart from those uprushes of faith from the subconscious whereof we have spoken in previous lectures, there are for James no other tests of the truth

of religious convictions than these. The truth of religion consists in its successful "workings."

Hence, however, religion depends upon an ever-renewed testing of its opinions through a carrying of them out in life. Insight would be barren were it not quickened and applied through our will. To James, as we already know, reason, as such, seems to be of little use in religion. But action, resolute living, testing of your faith through your works and through its own workings, this is religion – an endlessly restless and dramatic process, never a union with any absolute attainment of the goal.

V

Now in what way can I hope, you may ask, to answer these impressive and to many recent writers decisive considerations of the pragmatists? My answer, like my foregoing statement of my own form of idealism, depends upon extremely simple considerations. Their interest for our discussion lies in the fact that they have to do with the relation between reason and action, and between the real world and the human will. As a fact, the will as well as the reason is a source of religious insight. No truth is a saving truth – yes, no truth is a truth at all unless it guides and directs life. Therein I heartily agree with current pragmatism and with James himself. On the other hand, the will is a collection of restless caprices unless it is unified by a rational ideal. And no truth can have any workings at all, without even thereby showing itself to be, just in so far as it actually works, an eternal truth. And, furthermore, what I have asserted about the insight which the reason gives us is so far from being opposed to the pragmatist's facts, that every rational consideration of the type of truth which they define leads us back to the consideration of absolute truth and to the assertion of an all-inclusive insight. Only, when we view this all-inclusive insight from the point of view which the pragmatists now emphasize (and which I myself have emphasized from a period long antedating the recent pragmatist movement), such a fair estimate of the insight of reason transforms our first and superficial opinion of its nature and of its meaning. It becomes the insight of a rational will, whose expression is the world, and whose life is that in which we too live and move and have our being.

Let me briefly dwell on each of the considerations which I here have in mind. To me, as a philosophical student, they are not new; for, as I repeat, I insisted upon them years ago, before the modern pragmatist controversy began.

First, then, there are certain respects in which I fully agree with recent pragmatism. I agree that every opinion expresses an attitude of the will, preparedness for action, a determination to guide a plan of action in accordance with an idea. Whoever asserts anything about the way out of the woods, or about the cause and possible cure of a toothache, defines a course

of action in accordance with some purpose, and amongst other things predicts the possible outcome of that course of action. The outcome that he predicts is defined in terms of experience, and, so far as that is possible, in terms of human experience. And now this is true, not only of assertions or opinions about toothaches. It is true also of assertions about all objects in heaven or earth. There is no such thing as a purely intellectual form of assertion which has no element of action about it. An opinion is a deed. It is a deed intended to guide other deeds. It proposes to have what the pragmatists call "workings." That is, it undertakes to guide the life of the one who asserts the opinion. In that sense, all truth is practical. If you assert a proposition in mathematics, you propose to guide the computations, or other synthetic processes, of whoever is interested in certain mathematical objects. If you say "There is a God," and know what you mean by the term "God," you lay down some sort of rule for such forms of action as involve a fitting acknowledgment of God's being and significance. So far, then, I wholly side with the pragmatists. There is no pure intellect. There is no genuine insight which does not also exist as a guide to some sort of action.

Furthermore, the proper "workings" of an assertion, the rational results of the application of this opinion to life, must, if the assertion is true, agree with the expectations of the one who defines the assertion. And these "workings" belong, indeed, to the realm of actual and concrete experience, be this experience wholly human, or be it, in some respect, an experience which is higher and richer than any merely human experience. Opinions are active appeals to real life – a life to which we are always seeking to adjust ourselves, and in which we are always looking to find our place. The quest for salvation itself is such an effort to adjust our own life to the world's life. And if the world's life finds our efforts to define our relation to the world's actual and perfectly concrete experience inadequate, then our assertions are in just so far false; they lead in that case to blundering actions. We fail. And in such cases our opinions, indeed, "do not work."

All this I myself insist upon. But next I ask you to note that the very significance of our human life depends upon the fact that we are always undertaking to adjust ourselves to a life, and to a type of experience, which, concrete and real though it is, is never reducible to the terms of any purely human experience. Were this not the case; were not every significant assertion concerned with a type and form of life and of experience which no man ever gets; were not all our actions guided by ideas and ideals that can never be adequately expressed in simply human terms; were all this, I say, not the case, then – neither science nor religion, neither worldly prudence nor ideal morality, neither natural common-sense nor the loftiest forms of spirituality would be possible. Here I can only repeat, but now with explicit reference to the active aspect of our opinions and of our experience, the comments that I made in my former lecture. Man as he is experiences from moment to

moment. What is here and now, not future "workings," not past expectations, but the present – this is what he more immediately gets and verifies. These momentary experiences of his, these pains and these data of perception, are what he can personally verify for himself. And to this life in each instant he is confined, so far as his own personal and individual experience is concerned. But man *means*, he *intends*, he *estimates*, he *judges* life, not as it appears to him at any one instant, but as "in the long run," or "for the common-sense of mankind," or as "from a rational point of view" he holds that it ought to be judged. Now I again insist – there is not one of us who ever directly observes in his own person what it is which even the so-called common-sense of mankind is said to verify and find to be true. The experience which "mankind" is said to possess is not merely the mere collection of your momentary feelings or perceptions, or mine. It is a conceived integral experience which no individual man ever gets before him. When we conceive it, we first treat it as something impersonal. If it is personal, the person who gets it before him is greater than any man. Yet unless some such integral experience is as concrete and genuine a fact, as real a life, as any life that you and I from moment to moment lead, then all so-called "common-sense" is meaningless. But if such an integral experience is real, then that by which the pragmatic "workings" of our private and personal opinions are to be tested and are tested is a certain integral whole of life in which we all live and move and have our being, but which is no more the mere heap and collection of our moments of fragmentary experience, and of our vicissitudes of shifting moods, than a symphony is a mere collection of notes on paper, or of scraped strings and quivering tubes, or of air waves, or even of the deeds of separate musicians.

The life, then, the experience, the concrete whole, wherein our assertions have their workings, with which our active ideas are laboring to agree, to which our will endlessly strives to adjust itself, in which we are saved or lost, is a life whose touch with our efforts is as close as its superiority to our merely human narrowness is concretely and actively triumphant whenever our pettiness gets molded to a higher reasonableness. And unless such a life above our individual level is real, our human efforts have no sense whatever, and chaos drowns out the meaning of the pragmatists and of the idealists alike. *If one asks, however, by what workings our significant assertions propose to be judged, I answer, by their workings as experienced and estimated from the point of view of such a larger life, as conforming to its will, or falling short thereof, as leading toward or away from our salvation.* For it is just such a larger life by which we all propose and intend to be judged, whenever we make our active appeal to life take the form of any serious assertion whatever. If a man proposes to let his ideas be tested not by his momentary caprice, and not by any momentary datum of experience, but by "what proves to be their workings in the long run," then already he is

appealing to an essentially superhuman type of empirical test and estimate. For no man taken as this individual ever personally experiences "the long run," that is, the integral course and meaning, the right estimate and working of a long series of experiences and deeds. For a man individually observes now this moment and now that – never their presupposed integration, never their union in a single whole of significant life.

If a man says that the workings of his ideas are to be tested by "scientific experience," then again he appeals not to the verdict of any human observer, but to the integrated and universalized and relatively impersonal and super-personal synthesis of the results of countless observers.

And so, whatever you regard as a genuine test of the workings of your ideas is some living whole of experience above the level of any one of our individual human lives. To this whole you indeed actively appeal. The appeal is an act of will. And in turn you regard that to which you appeal as an experience which is just as live and concrete as your own, and which carries out its own will in that it snubs or welcomes your efforts with a will as hearty as is your own. For what estimates your deeds, and gives them their meaning, is a life as genuine as yours and an activity as real as yours. Pragmatism is perfectly justified in regarding the whole process as no mere contemplation, no merely restful or static conformity of passive idea to motionless insight, but, on the contrary, as a significant interaction of life with life and of will with will. But the more vital the process, the more pragmatic the test of our active opinions through the conformity or non-conformity of their purposes to the life wherein we dwell and have our being, the more vital becomes the fact that, whether we are saved or lost, we belong to the world's life, and are part thereof, while, unless this life is more than merely human in its rational wealth of concrete meaning, we mortals have no meaning whatever, and the assertions of common-sense as well as of religion lapse into absurdity.

VI

In order fairly to estimate aright our relation to this larger life, we must briefly review the further thesis upon which recent pragmatism lays so much stress – the thesis that, since the truth of an opinion consists in the agreement or disagreement of its empirical workings with their anticipated consequences, all truth is both temporal and relative and cannot be either eternal or absolute. Let me then say a word as to the absoluteness of truth.

The thesis of pragmatism as to the active nature and the practical meaning of all opinions may be illustrated by a simile that, as I think, well brings out the sense in which, as I hold, pragmatism itself is a true doctrine. Any sincere opinion announces a plan of action whereby we are, in some way, to adjust ourselves for some purpose to a real object. That is, an opinion lays down, in some form, a rule for some sort of conduct. This rule is of course valid only

for one who has some specific interest in the object in question. For you can guide action only by appealing to the will of the one whom you guide. This is the pragmatist's view of the nature of all assertions and opinions. And so far, as you already know, I agree with the pragmatist. This account is correct.

This being so, we can, for the sake of a simile, compare any definite opinion to the counsel that a coach may give to a player whom he is directing. The player wants to play the game." He therefore accepts its rules, and has his interests in what the pragmatists call "the concrete situation." The player, at any point in his training or in his activities as a player, may also accept the coach's guidance, and put himself under the coach's directions. If, hereupon, the player acts in accordance with what the coach ordains, the coach's directions have "workings." Their "workings" are in so far the deeds of the player. These deeds, if the issues of the game are sharply defined, are what we may call hits or misses. That is, each one of them either is what, for the purposes of the game and the player, it ought to be, or else it is not what it ought to be. And each act of the player is a hit or a miss in a perfectly objective sense, as a real deed belonging to a world whose relations are determined by the rules and events of the game and by the purposes of the whole body of players.

Applying the simile to the case of assertions, we may say: An assertion is an act whereby our deeds are provided with a sort of coaching. Life itself is our game. Opinions coach the active will as to how to do its deed. If the opinion is definite enough, and if the active will obeys the coach, the opinion has "workings." These workings are our intelligent deeds, which translate our opinions into new life. If our purposes are definite enough, and if the issues of life are for us sharply defined, these deeds are, with reference to our purposes, either hits or misses, either successful or unsuccessful acts, either steps toward winning or steps toward failure. All this is surely concrete enough. And, in real life, this account applies equally to the practical situations of the workshop or of the market-place, and to the ideas and deeds of a religious man seeking salvation.

But now one of the central facts about life is that every deed once done is *ipso facto* irrevocable. That is, at any moment you perform a given deed or you do not. If you perform it, it is done and cannot be undone. This difference between what is done and what is left undone is, in the real and empirical world, a *perfectly absolute difference*. The opportunity for a given individual deed returns not; for the moment when that individual deed can be done never recurs. Here is a case where the rational constitution of the whole universe gets into definite relation to our momentary experience. *And if any one wants to be in touch with the "Absolute" – with that reality which the pragmatists fancy to be peculiarly remote and abstract – let him simply do any individual deed whatever and then try to undo that deed. Let the experiment teach him what one means by calling reality absolute. Let the truths which*

that experience teaches any rational being show him also what is meant by absolute truth.

For this irrevocable and absolute character of the deed, when once done, rationally determines an equally irrevocable character about the truth or falsity of any act of judgment, of any assertion or opinion, which has actually called in a concrete situation for a given deed, and which therefore has had this individual deed for any part of its intended "workings." Let us return to the simile of the game. Suppose the coach to counsel a given deed of the player. Suppose the player, acting on the coach's advice, to perform that deed, to make that play. Suppose the play to be a misplay. The play, once made, cannot be recalled. It stands, if the rules of the game require it so to stand, on the score. If it stands there, then just *that* item of the score can never be changed under the rules of the game. The score is, for the game, absolute and irrevocable. If the coach counseled that misplay, his counsel was an error. And just as the player's score cannot be changed without simply abandoning the rules of the game, so too the coach's record as a blunderer is, in respect of this one bit of counsel, unalterable. Analogous results hold for the player's successful hits and for the coaching that required them. All this is no result of abstractions or of bare theory. It is the result of having the will to play the game. It is the absolute truth that results from joining definite practical issues.

Returning to life, we must say: If our assertions have a determinate meaning, they get their concrete workings through counseling determinate individual deeds. Each deed, as an individual act, is irrevocable and is absolutely what it is. Our deeds, judged in the light of a reasonable survey of life – a survey of life such as that to which, when we form our opinions, and when we act on our opinions, we intend to appeal – are, for a determinate purpose, either hits or misses. If the issues of life in question when we act are definite enough, our deeds, under the rules of the game of life, cannot avoid this character of being the right deeds or the wrong deeds for the purpose in question and in view of their actual place in real life. Whoever so acts that his deeds are done, as a cant phrase has it, "with a string attached to them" – that is, whoever regards his deeds as having only relative reality, as capable of being recalled if he chooses, is not acting seriously. He is not, as they say, really "playing the game." And, as a fact, he is trifling with absolute reality. He is not only not serious; he views real life as it absolutely is not. For whatever individual deed he actually does is absolutely irrevocable, whether, he wants to recall it or not. Once done, it stands eternally on the world's score.

Now I insist, whatever assertion, or opinion, regarded as itself an expression of one's will, has for its intended working one of these irrevocable deeds, is in so far forth true, as the individual deed which it counsels is for the required purpose quite irrevocably a right deed when estimated with reference to this purpose and to the life into whose score it enters. That is, the opinion is true

in so far as the working which it counsels is a deed that is in fact a hit in the chosen game of life under the rules of that game. And whatever opinion counsels a deed that, as the working of this opinion, is a miss in the game of life, is a false opinion. And, so I insist, *this distinction between the truth and falsity of an opinion that counsels an individual deed is as absolute and irrevocable as is the place of the deed when once done on the score of the game of life.*

Whoever denies this position simply trifles with the very nature of all individual facts of experience; trifles also with life and with his own decisive will. Every serious man does his daily business with an assurance that, since his deeds are irrevocable, his guiding opinions, that counsel his individual deeds give, in an equally irrevocable way, right or wrong guidance, precisely in so far as they get their workings concretely presented in his deeds. And this view about life is no philosopher's abstraction. It is the only genuinely concrete view. Its contradiction is not merely illogical, but practically inane. I cannot do a deed and then undo it. Therefore I cannot declare it to be for a determinate purpose the right individual deed at this point in life, and then say that I did not really mean that counsel to be taken as simply and therefore absolutely true. Absolute reality (namely, the sort of reality that belongs to irrevocable deeds), absolute truth (namely, the sort of truth that belongs to those opinions which, for a given purpose, counsel individual deeds, when the deeds in fact meet the purpose for which they were intended) – these two are not remote affairs invented by philosophers for the sake of "barren intellectualism." *Such absolute reality and absolute truth are the most concrete and practical and familiar of matters.* The pragmatist who denies that there is any absolute truth accessible has never rightly considered the very most characteristic feature of the reasonable will, namely, that it is always counseling irrevocable deeds, and therefore is always giving counsel that is for its own determinate purpose irrevocably right or wrong precisely in so far as it is definite counsel.

One of the least encouraging features of recent discussion is the prominence and popularity of those philosophical opinions which are always proclaiming their "concrete" and "practical" character, while ignoring the most vital and concrete feature of all voluntary life. For the very essence of the will is that, at every moment of action, it decides absolute issues, because it does irrevocable deeds, and therefore, if intelligent at all, is guided by opinions that are as absolutely true or false as their intended workings are irrevocable. I repeat: If you want to know what an absolute truth is, and what an absolute falsity, do anything whatever, and then try to undo your deed. You will find that the opinion which should counsel you to regard it as capable of being undone gives you simply and absolutely false coaching as to any game of life whatever. Every effort to undo your deed is a blunder. Every opinion that you can undo is a trivial and absolutely false absurdity. Just such triviality and

absurdity belong to the thesis that absolute truth is an unpractical and inaccessible abstraction.

VII

If, with such a view of the nature of absolute truth, we turn back to estimate the sense in which our opinions about the world as a whole can be true or false, we now see that our account both of the insight of the reason, and of the nature of the world, has become enriched by this whole analysis of the nature of opinion. *Opinions about the universe are counsels as to how to adjust your deeds to the purposes and requirements which a survey of the whole of the life whereto your life belongs shows to be the genuinely rational purposes and requirements.* Every such opinion then, whether true or false, is an effort to adjust your will and your conduct to the intents of a supreme will which decides values, establishes the rule of life, and estimates purposes in the light of complete insight. That is, the insight to which your opinions appeal is indeed the insight of a real being who values, estimates, establishes, decides, as concretely as you do, and who is therefore not only all-wise, but possessed of a will. Your search for salvation is a seeking to adjust yourself to this supreme will. That such a will is real is as true as it is true that any opinion whatever which you can form with regard to the real world is either true or false. However ignorant you are, you are, then, in constant touch with the master of life; for you are constantly doing irrevocable deeds whose final value, whose actual and total success or failure, can only be real, or be known, from the point of view of the insight that faces the whole of real life, and with reference to the purposes of the will whose expression is the entire universe.

If, however, you say, with the pragmatists: "There is no whole world, there is no complete view, there is no will that wills the world; for all is temporal, and time flows, and novelties constantly appear, and the world is just now incomplete, and therefore there is nothing eternal," then my answer is perfectly definite. Of course there is, *just at this point of time*, no complete world. Of course, every new deed introduces novelties into the temporal world. But, on the other hand, even to assert this is to assert *that the future, and in fact all the future, in all its individual detail, belongs to reality, and forms part of its wholeness.* To admit this is to admit that the true insight, and the divine will, require, and get, *the endless whole of future time, as well as of past time, before them in one, not timeless, but time-inclusive survey, which embraces the whole of real life.* And just such a survey, and just such a life, not timeless, but time-inclusive, constitute the eternal, which is real, not apart from time, and from our lives, but in, and through and above all our individual lives. The divine will wills in us and in this entire world, with its endless past and its endless future, at once. The divine insight is not lifeless.

It includes and surveys all life. All is temporal in its ceaseless flow and in its sequence of individual deeds. All is eternal in the unity of its meaning.

To assert this, I insist, is not to deny our freedom and our initiative. The divine will wills me, precisely in so far as it wills that, in each of my individual deeds, I should then and there express my own unique, and in so far free, choice. And to assert, as I do, that the divine will wills all "at once" is not to assert that it wills all *at any one moment of time*, but only that the divine will is expressed in the totality of its deeds that are done in all moments of time.

But this, you will say, is still philosophy, not what the plain man needs for his religion. The question remains: Through what source of insight are we able to adjust our daily lives to this divine wisdom and to this divine will? I answer: Through a source of insight which is accessible to the plainest and simplest reasonable and sincere human being. Yet this source of insight, not yet expressly named in our study, includes in a beautiful and spiritual unity the true sense of our individual experience, of our social experience, of our reason, and of our will, and gives us at length a genuine religion. This new source we are to study in our next lecture.

THE WILL TO INTERPRET

"The Will to Interpret." *The Problem of Christianity* (New York: Macmillan, 1913), vol. 2, chap. 12, pp. 167–221.

We have seen some of the contrasts whereby the three cognitive processes: Perception, Conception, and Interpretation, are distinguished from one another. Our next task is to become better acquainted with the work and the value of Interpretation.

I

In this undertaking we shall be guided by the special problems to which our lectures are devoted. The metaphysical inquiry concerning the nature and the reality of the community is still our leading topic. To this topic whatever we shall have to say about interpretation is everywhere subordinate. But, since, if I am right, interpretation is indeed a fundamental cognitive process, we shall need still further to illustrate its nature and its principal forms. Every apparent digression from our main path will quickly lead us back to our central issues. Interpretation is, once for all, the main business of philosophy.

The present lecture will include two stages of movement towards our goal. First, we shall study the elementary psychology of the process of interpretation. Secondly, we shall portray the ideal that guides a truth-loving interpreter. The first of these inquiries will concern topics which are both familiar and neglected. The second part of our lecture will throw light upon the ethical problems with which our study of the Christian ideas has made us acquainted. At the close of the lecture our preparation for an outline of the metaphysics of interpretation will be completed.

II

I have called interpretation an essentially social cognitive process; and such, in fact, it is. Man is an animal that interprets; and therefore man lives in communities, and depends upon them for insight and for salvation.

But the elementary psychological forms in which interpretation appears find a place in our lives whether or no we are in company; just as a child can sing when alone, although singing is, on the whole, a social activity. We

shall need to consider how an interpreter conducts his mental processes, even when he is taking no explicit account of other minds than his own.

In looking for the psychological foundations of interpretation, we shall be directed by Charles Peirce's formal definition of the mental functions which are involved. Wherever an interpretation takes place, however little it seems to be an explicitly social undertaking, a triadic cognitive process can be observed. Let us look, then, for elementary instances of such triadic processes.

In the earliest of the logical essays to which, at the last time, I referred, Charles Peirce pointed out that every instance of conscious and explicit Comparison involves an elementary form of interpretation. This observation of Peirce's enables us to study interpretation in some of its simplest shapes, relieved of the complications which our social efforts to communicate with other minds usually involve.

Yet, even in this rudimentary form, interpretation involves the motives which, upon higher levels, make its work so wealthy in results, and so significant in its contrasts with perception and conception.

III

The most familiar instances of the mental process known as Comparison seem, at first sight, to consist of a consciousness of certain familiar dyadic relations, – relations of similarity and difference. Red contrasts with green; sound breaks in upon silence; one sensory quality collides, as it were, with another. The "shock of difference" awakens our attention. In other cases, an unexpected similarity of colors and tones attracts our interest. Or perhaps the odors of two flowers, or the flavors of two fruits, resemble one the other. Pairs of perceived objects are, in all these cases, in question. We express our observations in such judgments as: "A resembles B"; "D is unlike E."

Now Peirce's view of the nature of comparison depends upon noticing that, familiar as such observations of similarity and dissimilarity may be, no one of them constitutes the whole of any complete act of comparison. Comparison, in the fuller sense of the word, takes place when one asks or answers the question: What constitutes the difference between A and B?" "*Wherein* does A resemble B?" "*Wherein* consists their distinction?" Let me first illustrate such a question in a case wherein the answer is easy.

If you write a word with your own hand, and hold it up before a mirror, your own handwriting becomes more or less unintelligible to you, unless you are already accustomed to read or to write mirror-script. Suppose, however, that instead of writing words yourself, you let some one else show you words already written. And suppose, further, that two words have been written side by side on the same sheet of paper, neither of them by your own hand. Suppose one of them to have been written upright, while the other is the counterpart of the first, except that it is the first turned upside down, or else

is the first in mirror-script. If, without knowing how these words have been produced, you look at them, you can directly observe that the two written words differ in appearance, and that they also have a close resemblance. But, unless you were already familiar with the results of inverting a handwriting or of observing it in a mirror, you could not thus directly observe wherein consist the similarities and the differences of the two words which lie before you on the paper.

Since you are actually familiar with mirror-script, and with the results of turning a sheet of paper upside down, you will indeed no doubt be able to name the difference of the two supposed words. But in order to compare the two words thus presented side by side on the same sheet of paper, and to tell wherein they are similar and wherein they differ, you need what Peirce calls a mediating idea, or what he also calls "a third," which, as he phrases the matter, shall "represent" or "interpret" one of the two written words to, or in terms of, the other. You use such a "third" idea when you say, "This word is the mirror-script representative of that word." For now the difference is interpreted.

Thus a complete act of comparison involves such a "third," such a "mediating" image or idea, – such an "interpreter." By means of this "third" you so compare a "first" object with a "second" as to make clear to yourself wherein consists the similarity and the difference between the second and the first. Comparison must be triadic in order to be both explicit and complete. Likenesses and differences are the signs that a comparison is needed. But these signs are not their own interpretation.

Let us observe another instance of the same general type. One may be long acquainted with the difference between his own right and left hands before one learns to interpret this difference, and so to complete one's comparison, in terms of the third idea that the one hand is a more or less imperfect mirror-image of the other hand, the imperfections being due to the lack of symmetry in our bodily structure.

Still another familiar instance of comparison will show how needful it is to choose the right "third" in order to complete one's view of the matter. One may long have observed that a friend's face, when seen in a mirror, contrasts with the same face if seen apart from the mirror. Yet it may be very hard for a given person to tell why this difference exists, or wherein it consists. I have asked the question of various intelligent and observant people, who could only reply: "It is true that in general a man's face, as I see it before me, does not perfectly resemble that man's face as it appears when I look at it in a mirror. But I cannot define the reason for this difference, or tell wherein the difference consists." The answer to the question is that, since the features of a human face are usually, in their finer details, more or less unsymmetrically disposed with reference to the vertical axis of the body, the mirror picture, even of a fairly regular countenance, must be altered to suit these vertical asymmetries.

The idea of the vertical asymmetries is here the needed "third" which interprets the difference between the man's face when seen in the mirror and when seen out of the mirror.

A lady who had passed part of her life in Australia, and part in England, once told me that, for years, she had never been able to understand the difference which, to her eyes, existed between the full moon as seen in England and as observed by her during her years in Australia. At last she found the right mediating idea, when she came to notice how Orion also gradually became partially inverted during her journeys from English latitudes to those of the far southern seas. For the full moon, as she thus came to know, must be subject to similar apparent inversions; and this was the reason why the "man in the moon" had therefore been undiscoverable when she had heretofore looked for him in Australian skies.

IV

When processes of comparison grow complicated, new "third" terms or "mediators" may be needed at each stage of one's undertaking. So it is when a literary parallel between two poets or two statesmen is in question. Now one and now another trait or event or fortune or deed may stand out as the mediating idea. But always, in such parallels, it is by means of the use of a "third" that each act of comparison is made possible, – whether the case in question be simple or complex. And the mediator plays each time the part which Peirce first formally defined.

Let there arise the problem of drawing a literary parallel between Shakespeare and Dante. The task appears hopelessly complex and indeterminate until, perhaps, the place which the sonnet occupied in the creative activity of each poet comes to our minds. Then indeed, although the undertaking is still vastly complicated, it is no longer quite so hopeless. If "with this key Shakespeare unlocked his heart," yet held fast its deepest mysteries; while Dante accompanied each of the sonnets of the *Vita Nuova* with a comment and an explanation, yet left unspoken what most fascinates us in the supernatural figure of his beloved, – then "the sonnet," viewed as an idea of a poetical form, mediates between our ideas of the two poets, and represents or interprets each of these ideas to the other.

This last example suggests an endless wealth of complexities. And the interpretation in question is also endlessly inadequate to our demands. But on its highest levels, as in its simplest instances, the process of explicit comparison is thus triadic, and to notice this fact is, for the purpose of our study of comparison, illuminating.

For when we merely set pairs of objects before us, and watch their resemblances and differences, we soon lose ourselves in mazes. Yet even when the mazes are indeed not to be penetrated by any skill, still a triadic comparison

is much more readily guided towards the light. "How does A differ from C?" If you can reply to this question by saying that, by means of B, A can be altogether transformed into C, or can, at least, be brought into a close resemblance to C, then the comparison of A to C is made definite.

Let me choose still one more illustration of such a comparison. This time the illustration shall not come from the literary realm; yet it shall be more complex than is the instance of the comparison between a written word and its image in the mirror.

If you cut a strip of paper, – perhaps an inch wide and ten inches long, – you can bring the two ends together and fasten them with glue. The result will be a ring-strip of paper, whose form is of a type very familiar in case of belts, finger-rings, and countless other objects. But this form can be varied in an interesting way. Before bringing the ends of the strip together, let one end of the paper be turned 180°. Holding the twisted end of the strip fast, glue it to the other. There now results an endless strip of paper having in it a single twist. Lay side by side an ordinary ring-strip that has no twist, and a ring-strip of paper that has been made in the way just indicated. The latter strip has a single twist in it. Hereupon ask a person who has not seen you make the two ring-strips, to compare them, and to tell you wherein they agree and wherein they differ.

To your question an ordinary observer, to whom this new form of ring-strip is unfamiliar, will readily answer that they obviously differ because one of them has no twist in it, while the other certainly has some kind of twist belonging to its structure. So far the one whom you question indeed makes use of a "third" idea. But this idea probably remains, so far, vague in his mind, and it will take your uninformed observer some time to make his comparison at all complete and explicit.

In order to aid him in his task, you may hereupon call his attention to the further fact that the ring-strip which contains the single twist has two extraordinary properties. It has, namely, but one side; and it also has but one edge. The mention of this fact will at first perplex the uninitiated observer. But when he has taken the trouble to study the new form, he will find that the idea of a "one-sided strip of paper" enables him to compare the new and the old form, and to interpret his idea of the new ring-form to his old idea of an ordinary ring such as has no twist, and possesses two sides.

V

In all the cases of explicit comparison which we have just considered, what takes place has, despite the endless varieties of circumstance, an uniform character.

Whoever compares has before him what we have called two distinct ideas; perhaps his ideas of these two printed or written words; or again, his ideas

of these two ring-strips of paper; or, in another instance, his ideas of Dante and of Shakespeare.

And the term "idea" is used, in the present discussion, in the sense which James and other representative pragmatists have made familiar in current discussion. Let us then hold clearly in mind this definition of the term "idea." For we shall even thereby be led to note facts which will lead us beyond what this definition emphasizes.

An idea, in this sense, is a more or less practical and active process, a "leading," as James calls it, whereby some set of conceptions and perceptions tend to be brought into desirable connections. An idea may consist mainly of some effort to characterize the data of perception through the use of fitting conceptions. Or, again, an idea may be a prediction of future perceptions. Or, an idea may be an active seeking for a way to translate conceptual "bank-notes" into perceptual cash. In any one idea, either the perceptual or the conceptual elements may, at any one moment, predominate. If the conceptual element is too marked for our purposes, the idea stands in need of perceptual fulfilment. If the perceptual element is too rich for our momentary interests, the idea needs further conceptual clarification. In any case, however, according to this view, the motives of an idea are practical, and the constituents of an idea are either the data of perception, or the conceptual processes whereby we characterize or predict or pursue such data.

But when, in Peirce's sense of the word, we have to make an explicit comparison, we have before us two distinct and contrasting ideas. It is their distinctness, it is their contrast, which determines our task. And these ideas involve, in general, not only different perceptual and different conceptual constituents, but also different and sometimes conflicting "leadings," different and sometimes mutually clashing interests, various and mutually estranged motives, activities, or constructions. These two ideas may contrast as do two forms of art. Or they may stand out the one over against the other as if they were two geometrical structures. They may collide as do two warring passions. They may first meet as simple strangers in our inner world. Their relations may resemble those of plaintiff and defendant in a suit at law. Or they may be as interestingly remote from one another as are the spiritual realms of two great poets. In such endlessly various fashions may the two ideas come before us.

The essential fact for our present study is that, in case of the comparisons which Peirce discusses, the problem, whether you call it a theoretical or a practical problem, is not that of linking percepts to their fitting concepts, nor that of paying the bank bills of conception in the gold of the corresponding perceptions. On the contrary, it is the problem, either of arbitrating the conflicts; or of bringing to mutual understanding the estrangements; or of uniting in some community the separated lives of

these two distinct ideas, – of ideas which, when left to themselves, decline to coalesce or to coöperate, or to enter into one life.

This problem, in the cases of comparison with which Peirce deals, is solved through a new act. For this act originality and sometimes even genius may be required. This new act consists in the invention or discovery of some third idea, distinct from both the ideas which are to be compared. This third idea, when once found, interprets one of the ideas which are the objects of the comparison, and interprets it to the other, or in the light of the other. What such interpretation means, the instances already considered have in part made clear. But the complexity and the significance of the processes involved require a further study. And this further study may here be centered about the question: What is gained by the sort of comparison which Peirce thus characterizes? And, since we have said that all such comparison involves an activity of interpreting one idea in the light of another, we may otherwise state our question thus: What, in these cases of comparison, is the innermost aim of the Will to Interpret which all these processes of comparison manifest?

VI

The rhythm of the Hegelian dialectic, wherein thesis, antithesis, and higher synthesis play their familiar parts, will here come to the minds of some who follow my words; and you may ask wherein Peirce's processes of comparison and interpretation differ from those dialectical movements through division into synthesis, which Hegel long since used as the basis of his philosophy. I reply at once that Peirce's theory of comparison, and of the mediating idea or "third" which interprets, is, historically speaking, a theory not derived from Hegel, by whom at the time when he wrote these early logical papers, Peirce had been in no notable way influenced. I reply, further, that Peirce's concept of interpretation defines an extremely general process, of which the Hegelian dialectical triadic process is a very special case. Hegel's elementary illustrations of his own processes are ethical and historical. Peirce's theory of comparison is quite as well illustrated by purely mathematical as by explicitly social instances. There is no essential inconsistency between the logical and psychological motives which lie at the basis of Peirce's theory of the triad of interpretation, and the Hegelian interest in the play of thesis, antithesis, and higher synthesis. But Peirce's theory, with its explicitly empirical origin and its very exact logical working out, promises new light upon matters which Hegel left profoundly problematic.

Returning, however, to those illustrations of Peirce's theory of comparison which I have already placed before you, let us further consider the motives which make a comparison of distinct and contrasting ideas significant for the one who compares.

An idea, as I have said, is, in James's sense, a practical "leading." An idea, if, in James's sense, successful, and if successfully employed, leads through concepts to the desirable or to the corresponding percepts. But a comparison of ideas – that, too, is no doubt an active process. To what does it lead? It leads, as we have seen, to a new, to a third, to an interpreting idea. And what is this new idea? Is it "cash," or has it only "credit-value"? What does it present to our view? What does it bring to our treasury?

One must for the first answer this question in a very old-fashioned way. The new, the third, the interpreting idea, in these elementary cases of comparison, shows us, as far as it goes, ourselves, and also creates in us a new grade of clearness regarding what we are and what we mean. First, I repeat, the new or third idea shows us ourselves, as we are. Next, it also enriches our world of self-consciousness. It at once broadens our outlook and gives our mental realm definiteness and self-control. It teaches one of our ideas what another of our ideas means. It tells us how to know our right hand from the left; how to connect what comes to us in fragments; how to live as if life had some coherent aim. All this is indeed, thus far, very elementary information about what one gains by being able to hold three ideas at once in mind. But, in our own day, such information is important information. For our age, supposing that the contrast between perception and conception exhausts the possible types of cognitive processes, is accustomed to listen to those who teach us that self-knowledge also must be either intuitive (and, in that case, merely fluent and transient) or else conceptual (and, in that case, abstract and sterile).

But a dual antithesis between perceptual and conceptual knowledge is once for all in adequate to the wealth of the facts of life. When you accomplish an act of comparison, the knowledge which you attain is neither merely conceptual, nor merely perceptual, nor yet merely a practically active synthesis of perception and conception. It is a third type of knowledge. It interprets. It surveys from above. It is an attainment of a larger unity of consciousness. It is a conspectus. As the tragic artist looks down upon the many varying lives of his characters, and sees their various motives not interpenetrating, but coöperating, in the dramatic action which constitutes his creation, – so any one who compares distinct ideas, and discovers the third or mediating idea which interprets the meaning of one in the light of the other, thereby discovers, or invents, a realm of conscious unity which constitutes the very essence of the life of reason.

Bergson, in his well-known portrayal, has glorified instinct in its contrast with the intellect. The intellect, as he holds, is a mere user of tools. Its tools are concepts. It uses them in its practical daily work to win useful percepts. It loves to be guided in its daily industries by rigid law. It is therefore most at home in the realm of mechanism and of death. Life escapes its devices. Its concepts are essentially inadequate. Instinct, on the contrary, so far as man

still preserves that filmy cloud of luminous instinct and of intuition which, in Bergson's opinion, constitutes the most precious resource of genius, perceives, and sympathizes, and so comes in touch with reality.

That this account of the cognitive process is inadequate, both the artist and the prophets combine with the scientific observers of nature, with the mathematicians, and with the great constructive statesmen, to show us. Comparison is the instrument of what one may call, according to one's pleasure, either the observant reason, or the rational intuition whereby the world's leading minds have always been guided. And it is comparison, it is interpretation, which teaches us how to deal with the living, with the significant, and with the genuinely real.

Darwin, for instance, as a naturalist, saw, compared, and mediated. We all know how the leading ideas of Malthus furnished the mediating principle, the third, whereby Darwin first came to conceive how the contrasting ideas with which his hypotheses had to deal could be brought into unity. And that such comparison is peculiarly adapted to deal with the phenomena of life, let not only the genesis of Darwin's ideas, but the place of the process of comparison in the development of all the organic sciences, show.

If we turn to the other extreme of the world of human achievement, in order to learn what is the sovereign cognitive process, we shall find the same answer. For let us ask, – By means of what insight did Amos the prophet meet the religious problems of his own people and of his own day? He faced tragic contrasts, moral, religious, and political. Warring ideas were before him, – ideas, each of which sought its own percepts, through its own concepts of God, of worship, and of success. But Amos introduced into the controversies of his time the still tragic, but inspiring and mediating, idea of the God who, as he declared, delights not in sacrifices but in righteousness. And by this one stroke of religious genius the prophet directed the religious growth of the centuries that were to follow.

Think over the burial psalm, or the Pauline chapters on Charity and the Resurrection, if you would know what part comparison and mediation play in the greatest expressions of the religious consciousness. Remember Lear or the Iliad, if you wish to recall the functions of contrast and of mediation in poetry. Let the Sistine Madonna or Beethoven's Fifth Symphony illustrate the same process in other forms of the artistic consciousness.

If once you have considered a few such instances, then, summing up their familiar lessons, you may note that in none of these cases is it conception, in none of them is it bare perception, least of all is it inarticulate intuition, which has won for us the greatest discoveries, the incomparable treasures in science, in art, or in religion.

The really creative insight has come from those who first compared and then mediated, who could first see two great ideas at once, and then find the new third idea which mediated between them, and illumined.

We often use the word "vision" for this insight which looks down upon ideas as from above, and discovers the "third," thereby uniting what was formerly estranged. If by the word "intuition" one chooses to mean this grade of insight, then one may indeed say that creative mental prowess depends, in general, upon such intuition. But such intuition is no mere perception. It is certainly not conception. And the highest order of genius depends upon reaching the stage of Peirce's "third" type of ideas. Comparison, leading to the discovery of that which mediates and solves, and to the vision of unity, is the psychological basis of poetry, as Shakespeare wrote, and of such prophecy as Paul praised when he estimated the spiritual gifts. Comparison, then, and interpretation constitute the cognitive function whereby we deal with life. Instinct and bare perception, left to themselves, can never reach this level.

VII

When we consider the inner life of the individual man, the Will to Interpret appears, then, as the will to be self-possessed. One who compares his own ideas, views them as from above. He aims to pass from blind "leadings" to coherent insight and to resolute self-guidance. What one wins as the special object of one's insight depends, in such cases, upon countless varying psychological conditions, and upon one's success in finding or in inventing suitable mediators for the interpretation of one idea in the light of another. It may therefore appear as if in this realm of interior comparisons, where the objects compared are pairs of ideas, and where results of comparison consist in the invention of a third, there could be no question of attaining fixed or absolute truth. If anywhere pragmatism could be decisively victorious; if anywhere the purely relative and transient would seem in possession of the field, – one might suppose that comparison would constantly furnish us with instances of relative, shifting, and fluent truth.

As a fact, however, this is not the case. Comparison, which is so powerful an instrument in dealing with life, and with the fluent and the personal, is also perfectly capable of bringing us into the presence of the exact and of the necessary. All depends upon what ideas are compared, and upon the purpose for which they are compared, and upon the skill with which the vision of unity is attained.

Let the comparison of the two ring-strips of paper show what I here have in mind. The difference between a ring-strip which contains a single twist, and another which is constructed in the usual way, seems at first sight to be both insignificant and inexact. A closer study shows that the geometry of surfaces that possess but a single side can be developed into as exact a branch of pure mathematics as you can mention. The development in question would depend upon assuming, quite hypothetically, a few simple principles which are suggested, although not indeed capable of being proved, by experience of the

type which recent pragmatism has well analyzed. The branch of pure mathematics in question would consist of deductions from these few simple principles. The deductions would interpret these principles, viewed in some sort of unity and compared together.

But recent pragmatism has not well analyze the process whereby, in pure mathematics, the consequences which follow from a set of exactly stated hypotheses are determined. This process, the genuine process of deduction, depends upon a series of ideal experiments. These experiments are performed by means of putting together ideas, two and two, by comparing the ideas that are thus brought together, by discovering mediators, and by reading the results of the combination. This process may lead to perfectly exact results which are absolutely true.

I know of no writer who has better or more exactly analyzed the way in which such ideal experiments can lead to novel and precise results than Peirce has done. His analysis of the deductive process was first made a good while since, and anticipated results which Mr. Bertrand Russell and others have since reached by other modes of procedure.

Peirce has shown that, when you interpret your combinations of ideas through ideal experiments, using, for instance, diagrams and symbols as aids, the outcome may be a truth as exact as the ideas compared are themselves exact. It may also be in your own experience as novel a result as your ideal experiment is novel. It may also be an absolute and immutable truth.

What you discover, in a case of deduction, is not that certain conclusions are, in themselves, considered true, but that they follow from, that they are implied by, certain hypothetically assumed premises. But a discovery that certain premises imply a certain conclusion, is the discovery of a fact. This fact may be found, not by perception, nor by conception, but by interpretation. None the less, it is a fact and it may be momentous.

It is customary to imagine that such a deductive process can get out of given premises nothing novel, but only (as people often say) – only what was already present in the premises. This customary view of deduction is incorrect. As Peirce repeatedly pointed out (long before any other writer had explicitly dealt with the matter), you can write out upon a very few sheets of paper all the principles which are actually used as the fundamental hypotheses that lie at the basis of those branches of pure mathematics which have thus far been developed. Yet the logical consequences which follow from these few mathematical hypotheses are so numerous that every year a large octavo volume in fine print is needed to contain merely the titles, and very brief abstracts, of the technical papers containing novel results which have been, during that year, published as researches in pure mathematics.

The mathematical papers in question embody, in general, consequences already implied by the few fundamental hypotheses which I have just

mentioned. An infinite wealth of still unknown consequences of the same principles remains yet to be explored and stated. All of these consequences can be won, in pure mathematics, by a purely deductive procedure.

Thus endlessly wealthy, thus possessed of an inexhaustible fecundity, is the genuine deductive process. Peirce long ago showed why. And while the mathematical procedure which is in question cannot here be further discussed, it is enough for our present purpose to indicate why this fecundity of deduction exists.

VIII

Deduction, in the real life of the exact sciences, is a process that recent pragmatism has no means of describing, simply because recent pragmatism is the prey of the dual classification of the cognitive processes, and views what it calls the "workings" of ideas merely in terms of the relations between conceptions and perceptions, – between "credit-values" and "cash-values."

Pragmatism, as James defined it, regards an idea as a "leading," whereby one pursues or seeks particulars; and whereby one sometimes obtains, and sometimes fails to obtain, the "cash-values" which one aims to get. Such a doctrine has no place for the understanding of what happens when, looking down as it were from above, one compares two ideas, and looks for a mediating idea. But just this is what happens in all cases of explicit comparison.

Now in the individual case, an interpretation, a mediating idea, may come to mind through almost any play of association, or as the result of almost any degree of skill in invention, or as the outcome either of serious or of playful combinations. In consequence, an interpretation may prove to be, in the single case, of purely relative and momentary truth and value.

But this, on the other hand, need not be the fortune of interpretation. The results of a comparison may express absolute truths, – truths which once seen can never be reversed. This absoluteness itself may be due to either one of two reasons.

In pure mathematics, a deduction, if correct at all, leads to an absolutely correct and irrevocably true discovery of a relation of implication between exactly stated premises and some conclusion. Deduction does this because deduction results from a comparison, and because the ideas compared may be, and in pure mathematics are, exact enough to suggest, at some moment, to the observant reasoner, an interpretation which, if it applies at all, applies universally to every pair of ideas identical in meaning with the pair of ideas here compared.

The act of comparison may be momentary, and may even be as an event, an accident. The inventive watcher of his own ideas may have been led to his deduction by whatever motive you please. But the interpretation, once discovered, may nevertheless represent a truth which is absolute precisely

because it is hypothetical. For the assertion: "P implies Q," or "If F, then Q," is an assertion about a matter of fact. And this assertion, if true at all, is always and irrevocably true about the same pair of ideas or propositions: P and Q.

Or again, the result of an interpretation may be absolutely true, because, for whatever reason, the interpretation in question counsels the one who makes the interpretation to do some determinate and individual deed. This deed may be such as to accomplish, at the moment when it is done, some ideally valuable result. But deeds once done are irrevocable. If, by interpreting your ideas in a certain way, at a certain moment, you have been led to do a worthy deed, – then the interpretation remains as irrevocably true as the good deed remains irrevocably done.

The principle, then, relating to the value and to the truth of one's acts of interior and conscious comparison, is that they express an insight which surveys, as from above, an unity wherein are combined various ideas. These ideas, as they first come, are pragmatic leadings which may be mutually estranged, or mutually hostile, or widely contrasted, or intimately interconnected. But, whatever the ideas may have been before they were compared, – as a result of the comparison of the two ideas, one of them is interpreted in the light of the other. The interpretation may possess all the exactness of mathematics, or all the transiency of a chance observation of the play of one's inner life. It may result in Paul's vision of the charity that never faileth, ruling supreme over the contrasts and the bickerings of passing passion; or it may solve a problem of comparative natural history or of comparative philology. Whatever the varieties of the cases in question, comparison can occur, and can reach truth, simply because we are wider than any of our ideas, and can win a vision which shall look down upon our own inner warfare, and upon our own former self-estrangements, as well as upon our own inner contrasts of exact definition. This vision observes not data of sense and not mere abstract concepts. Nor does it consist simply in our pragmatic leadings, and in their successes and failures. It observes what may interpret ideas to other ideas; as prophets and poets interpret to us what otherwise would remain, in seeming, hopelessly various and bewilderingly strange. It is not more intuition that we want. It is such interpretation which alone can enlighten and guide and significantly inspire. Upon the comparisons which thus interpret, our spiritual triumphs depend. Such triumphs are not merely the pragmatic successes of single ideas. They are the attainment of mastery over life.

IX

Our lengthy study of comparison and interpretation, as they are present in the inner life of the individual man, has prepared us for a new view of the social meaning of the Will to Interpret. Here I must once more take a temporary leave of Peirce's guidance, and trust to my own resources.

One who compares a pair of his own ideas may attain, if he is successful, that vision of unity, that grade of self-possession, which we have now illustrated. But one who undertakes to interpret his neighbor's ideas is in a different position.

In general, as we have seen, an interpreter, in his social relations with other men, deals with two different minds, neither of which he identifies with his own. His interpretation is a "third" or mediating idea. This "third" is aroused in the interpreter's mind through signs which come to him from the mind that he interprets. He addresses this "third" to the mind to which he interprets the first.

The psychology of the process of social interpretation, so far as that process goes on in the interpreter's individual mind, is identical with that psychology of comparison which we have now outlined. Nobody can interpret, unless the idea which he interprets has become more or less clearly and explicitly one of his own ideas, and unless he compares it with another idea which is, in some sense, his own.

But, from the point of view of the interpreter, the essential difference between the case where he is interpreting the mind of one of his neighbors to the mind of another neighbor, and the case wherein he is comparing two ideas of his own, is a difference in the clearness of vision which is, under human conditions, attainable.

When I compare two ideas of my own, the luminous self-possession which then, for a time, may come to be mine, forms for me an ideal of success in interpretation. This ideal I can attain only at moments. But these moments set a model for all my interpretations to follow.

When I endeavor to interpret my neighbor's mind, my interpretation has to remain remote from its goal. The luminous vision of the results of comparison comes to me, at best, only partially and with uncertainty. My neighbor's ideas I indeed in a measure grasp, and compare with other ideas, and interpret; but, as I do this, I see through a glass darkly. Only those ideas whose comparisons with other ideas, and whose resulting triadic interpretations I can view face to face, can appear to me to have become in a more intimate and complete sense my own individual ideas. When I possess certain ideas sufficiently to enable me to seek for their interpretation, but so that, try as I will, I can never clearly survey, as from above, the success of any of my attempted interpretations, – then these ideas remain, from my own point of view, ideas that never become wholly my own. Therefore these relatively alien ideas can be interpreted at all only by using the familiar hypothesis that they belong to the self of some one else. Under ordinary social conditions this other mind is viewed as the mind of my neighbor. Neither of my neighbor nor of myself have I any direct intuition. But of my own ideas I can hope to win the knowledge which the most successful comparisons exemplify. Of my neighbor's ideas I can never win, under human conditions, any interpre-

tation but one which remains hypothetical, and which is never observed, under these human conditions, as face to face with its own object, or with the idea of the other neighbors to whom the interpretation is addressed.

The Will to Interpret is, in our social relations, guided by a purpose which we are now ready to bring into close relations with the most significant of all the ethical ideals which, in our foregoing lectures, we have portrayed.

The interpreter, the mind to which he addresses his interpretation, the mind which he undertakes to interpret, – all these appear, in our explicitly human and social world, as three distinct selves, – sundered by chasms which, under human conditions, we never cross, and contrasting in their inner lives in whatever way the motives of men at any moment chance to contrast.

The Will to Interpret undertakes to make of these three selves a Community. In every case of ideally serious and loyal effort truly to interpret this is the simplest, but, in its deepest motives, the most purely spiritual of possible communities. Let us view that simple and ideal community as the interpreter himself views it, precisely in so far as he is sincere and truth-loving in his purpose as interpreter.

X

I, the interpreter, regard you, my neighbor, as a realm of ideas, of "leadings," of meanings, of pursuits, of purposes. This realm is not wholly strange and incomprehensible to me. For at any moment, in my life as interpreter, I am dependent upon the results of countless previous efforts to interpret. The whole past history of civilization has resulted in that form and degree of interpretation of you and of my other fellow-men which I already possess, at any instant when I begin afresh the task of interpreting your life or your ideas. You are to me, then, a realm of ideas which lie outside of the center which my will to interpret can momentarily illumine with the clearest grade of vision. But I am discontent with my narrowness and with your estrangement. I seek unity with you. And since the same will to interpret you is also expressive of my analogous interests in all my other neighbors, what I here and now specifically aim to do is this: I mean to interpret you to somebody else, to some other neighbor, who is neither yourself nor myself. Three of us, then, I seek to bring into the desired unity of interpretation.

Now if I could succeed in interpreting you to another man as fully as, in my clearest moments, I interpret one of my ideas to another, my process of interpretation would simply reduce to a conscious comparison of ideas. I should then attain, as I succeeded in my interpretation, a luminous vision of your ideas, of my own, and of the ideas of the one to whom I interpret you. This vision would look down, as it were, from above. In the light of it, we, the selves now sundered by the chasms of the social world, should indeed not interpenetrate. For our functions as the mind interpreted, the mind to whom

the other is interpreted, and the interpreter, would remain as distinct as now they are. There would be no melting together, no blending, no mystic blur, and no lapse into mere intuition. But for me the vision of the successful interpretation would simply be the attainment of my own goal as interpreter. This attainment would as little confound our persons as it would divide our substance. We should remain, for me, many, even when viewed in this unity.

Yet this vision, if I could win it, would constitute an event wherein your will to be interpreted would also be fulfilled. For if you are indeed ready to accept my service as interpreter, you even now possess this will to be interpreted. And if there exists the one to whom I can interpret you, that other also wills that you should be interpreted to him, and that I should be the interpreter.

If, then, I am worthy to be an interpreter at all, we three, – you, my neighbor, whose mind I would fain interpret, you, my kindly listener, to whom I am to address my interpretation, – we three constitute a Community. Let us give to this sort of community a technical name. Let us call it a Community of Interpretation.

The form of such a community is determinate.

One goal lies before us all, one event towards which we all direct our efforts when we take part in this interpretation. This ideal event is a goal, unattainable under human social conditions, but definable, as an ideal, in terms of the perfectly familiar experience which every successful comparison of ideas involves. It is a goal towards which we all may work together: you, when you give me the signs that I am to interpret; our neighbor, when he listens to my interpretation; I, when I devote myself to the task.

This goal: – Our individual experience of our successful comparisons of our own ideas shows us wherein it consists, and that it is no goal which an abstract conception can define in terms of credit-values, and that it is also no goal which a possible perception can render to me in the cash of any set of sensory data. Yet it is a goal which each of us can accept as his own. I can at present aim to approach that goal through plans, through hypotheses regarding you which can be inductively tested. I can view that goal as a common future event. We can agree upon that goal. And herewith I interpret not only you as the being whom I am to interpret, but also myself as in ideal the interpreter who aims to approach the vision of the unity of precisely this community. And you, and my other neighbor to whom I address my interpretation, can also interpret yourselves accordingly.

The conditions of the definition of our community will thus be perfectly satisfied. We shall be many selves with a common ideal future event at which we aim. Without essentially altering the nature of our community, our respective offices can be, at our pleasure, interchanged. You, or my other neighbor, can at any moment assume the function of interpreter; while I can pass to a new position in the new community. And yet, we three shall constitute as clearly as before a Community of Interpretation. The new

community will be in a perfectly definite relation to the former one; and may grow out of it by a process as definite as is every form of conscious interpretation.

Thus there can arise, in our community, no problem regarding the one and the many, the quest and the goal, the individual who approaches the goal by one path or by another, – no question to which the definition of the community of interpretation will not at once furnish a perfectly precise answer.

Such an answer will be based upon the perfectly fundamental triadic relation which is essential to every process of interpretation, whether such process takes place within the inner life of an individual human being, or goes on in the world of ordinary social intercourse.

XI

Thus, then, if I assume for the moment the rôle of an interpreter, I can define my office, my Community of Interpretation, and my place in that community.

It will be observed that the sort of truth which, as interpreter, I seek, cannot be stated in terms as simple as those with which the current pragmatism is satisfied. My interpretation, if I offer to our common neighbor any interpretation of your mind, will of course be an idea of my own, – namely, precisely that "third" idea which I contribute to our community as my interpretation of you. And no doubt I shall desire to make as sure as I can that this idea of mine "works." But no data of my individual perception can ever present to me the "workings" which I seek.

For I want my interpretation of you to our neighbor to be such as you would accept and also such as our neighbor would comprehend, were each of us already in the position of the ideal observer from above, whose vision of the luminous unity of my interpretation and its goal I am trying to imitate whenever I try to interpret your mind.

Thus, from the outset, the idea which I offer as my interpretation of your mind, is offered not for the sake of, or in the pursuit of, any individual or private perception of my own, either present or expected or possible. I am not looking for workings that could conceivably be rendered in my perceptual terms. I am ideally aiming at an ideal event, – the spiritual unity of our community. I can define that unity in perfectly empirical terms; because I have compared pairs of ideas which were my own, and have discovered their mediating third idea. But I do not expect to perceive that unity as any occurrence in my own individual life, or as any working of one of my own personal ideas. In brief, I have to define the truth of my interpretation of you in terms of what the ideal observer of all of us would view as the unity which he observed. This truth cannot be defined in merely pragmatic terms.

In a community thus defined, the interpreter obviously assumes, in a highly significant sense, the chief place. For the community is one of interpretation. Its goal is the ideal unity of insight which the interpreter would possess were these who are now his neighbors transformed into ideas of his own which he compared; that is, were they ideas between which his own interpretation successfully mediated. The interpreter appears, then, as the one of the three who is most of all the spirit of the community, dominating the ideal relations of all three members.

But the one who is, in ideal, this chief, is so because he is first of all servant. His office it is to conform to the mind which he interprets, and to the comprehension of the mind to which he addresses his interpretation. And his own ideas can "work" only if his self-surrender, and his conformity to ideas which are not his own, is actually a successful conformity; and only if his approach to a goal which, as member of a human community of interpretation, he can never reach, is a real approach.

XII

Such are the relationships which constitute a Community of Interpretation. I beg you to observe, as we close, the ethical and religious significance which the structure of such a community makes possible. In case our interpretations actually approach success, a community of interpretation possesses such ethical and religious significance, with increasing definiteness and beauty as the evolution of such a community passes from simpler to higher stages.

Upon interpretation, as we have already seen, every ideal good that we mortals win together, under our human social conditions, depends. Whatever else men need, they need their communities of interpretation.

It is indeed true that such communities can exist, at any time, in the most various grades of development, of self-consciousness, and of ideality. The communities of interpretation which exist in the market-places of the present social world, or that lie at the basis of the diplomatic intercourse of modern nations, are communities whose ideal goal is seldom present to the minds of their members; and it is not love which often seems to be their consciously ruling motive.

Yet, on the whole, it is not perception, and it is not conception; while it certainly is interpretation which is the great humanizing factor in our cognitive processes and which makes the purest forms of love for communities possible. Loyalty to a community of interpretation enters into all the other forms of true loyalty. No one who loves mankind can find a worthier and more significant way to express his love than by increasing and expressing among men the Will to Interpret. This will inspires every student of the humanities; and is present wherever charity enters into life. When Christianity teaches us to hope for the community of all mankind, we can readily see that the Beloved

Community, whatever else it is, will be, when it comes, a Community of Interpretation. When we consider the ideal form and the goal of such a community, we see that in no other form, and with no other ideal, can we better express the constitution of the ideal Church, be that conceived as the Church on earth, or as the Church triumphant in some ideal realm of superhuman and all seeing insight, where I shall know even as I am known.

And, if, in ideal, we aim to conceive the divine nature, how better can we conceive it than in the form of the Community of Interpretation, and above all in the form of the Interpreter, who interprets all to all, and each individual to the world, and the world of spirits to each individual.

In such an interpreter, and in his community, the problem of the One and the Many would find its ideally complete expression and solution. The abstract conceptions and the mystical intuitions would be at once transcended, and illumined, and yet retained and kept clear and distinct, in and through the life of one who, as interpreter, was at once servant to all and chief among all, expressing his will through all, yet, in his interpretations, regarding and loving the will of the least of these his brethren. In him the Community, the Individual, and the Absolute would be completely expressed, reconciled, and distinguished.

This, to be sure, is, at this point of our discussion, still merely the expression of an ideal, and not the assertion of a metaphysical proposition. But in the Will to Interpret, the divine and the human seem to be in closest touch with each other.

The mere form of interpretation may be indeed momentarily misused for whatever purpose of passing human folly you will. But if the ideal of interpretation is first grasped; and if then the Community of Interpretation is conceived as inclusive of all individuals; and as unified by the common hope of the far-off event of complete mutual understanding; and, finally, if love for this community is awakened, – then indeed this love is able to grasp, in ideal, the meaning of the Church Universal, of the Communion of Saints, and of God the Interpreter.

Merely to define such ideals is not to solve the problems of metaphysics. But it is to remove many obstacles from the path that leads towards insight.

These ideals, however, are grasped and loved whenever one first learns fully to comprehend what Paul meant when he said: "Wherefore let him that speaketh with tongues pray that he may interpret." This word is but a small part of Paul's advice. But in germ it contains the whole meaning of the office, both of philosophy and of religion.

THE DOCTRINE OF SIGNS

"The Doctrine of Signs." *The Problem of Christianity* (New York: Macmillan, 1913), vol. 2, chap. 14, pp. 279–325.

The Christian doctrine of life is dominated by the ideal of the Universal Community. Such was the thesis defended in the first part of this series of lectures. The real world itself is, in its wholeness, a Community. This was the metaphysical result in which our study of the World of Interpretation, at the last time, culminated.

I

Herewith the two assertions to which our study of the Problem of Christianity leads, are before you. Our concluding lectures must make explicit the relations between these two assertions. Hereby each of them will be interpreted in the light of the other.

Metaphysical theory and religious experience are always contrasting realms of inquiry and of insight. Therefore the task of our three concluding lectures constitutes a typical exercise in the process of interpretation. We have to compare results which have been reached by widely different methods. We have to mediate between them. The method of interpretation is always the comparative method. To compare and to interpret are two names for the same fundamental cognitive process.

The fitting order for such an enterprise is determined by the subject-matter. Since the metaphysical thesis with which our last lecture closed is very general, it will prove to be, indeed, a worthless abstraction, unless we illustrate its application to various special problems of life as well as of philosophy. What I can hope, within the limits of our brief remaining time, to make clearer, is what I may call the ground plan of the World of Interpretation.

The universe, if my thesis is right, is a realm which is through and through dominated by social categories. Time, for instance, expresses a system of essentially social relations. The present interprets the past to the future. At each moment of time the results of the whole world's history up to that moment are, so to speak, summed up and passed over to the future for its new deeds of creation and of interpretation. I state this principle here in a simply dogmatic form, and merely as an example of what I have in mind when I say that the system of metaphysics which is needed to define the constitution of

this world of interpretation must be the generalized theory of an ideal society. Not the Self, not the Logos, not the One, and not the Many, but the Community will be the ruling category of such a philosophy.

I must attempt, then, within our brief remaining time, to make this general metaphysical theory less abstract and more articulate. I must contrast our theory with others. I must make more explicit its relation to the Christian ideas. And then I must, in conclusion, survey what we have won, and summarize the outcome.

II

Let me begin by a few purely technical formulations. Charles Peirce, in the discussions which we have now so freely used, introduced into logic the term "Sign." He used that term as the name for an object to which somebody gives or should give an interpretation. I have not here to deal, at any length, with Peirce's development of his theory of Signs. His doctrine was, as you will recall, not at first stated as the basis for a metaphysical system, but simply as a part of a logical theory of the categories. My own metaphysical use of Pierce's doctrine of signs, in my account of the World of Interpretation at the last time, is largely independent of Peirce's philosophy. For the moment it is enough to say that, according to Peirce, just as percepts have, for their appropriate objects, individually existent Things; and just as concepts possess, for their sole objects, Universals, – so interpretations have, as the objects which they interpret, Signs. In its most abstract definition, therefore, a Sign, according to Peirce, is something that determines an interpretation. A sign may also be called an expression of a mind; and, in our ordinary social intercourse, it actually is such an expression. Or again, one may say that a sign is, in its essence, either a mind or a quasi-mind, – an object that fulfils the functions of a mind.

Thus, a word, a clock-face, a weather-vane, or a gesture, is a sign. Our reason for calling it such is twofold. It expresses a mind, and it calls for an interpretation through some other mind, which shall act as mediator between the sign, or between the maker of the sign, and some one to whom the sign is to be read.

Since an interpretation of a sign is, in its turn, the expression of the interpreter's mind, it constitutes a new sign, which again calls for interpretation; and so on without end; unless the process is arbitrarily interrupted. So much can be asserted as a purely logical thesis, quite apart from metaphysics. A sign, then, is an object whose being consists in the fact that the sign calls for an interpretation.

The process of interpretation, as it occurs in our ordinary social life, sufficiently illustrates the meaning of Peirce's new term. Peirce insists that the signs, viewed simply from a logical point of view, constitute a new and fundamen-

tally important category. He sets this category as a "third," side by side with the classic categories of the "universals" which form the "first" category, and the "individuals," which, in Peirce's logic, form the "second" category.

Peirce, as I have said, is not responsible for the metaphysical theory about the world of interpretation with which our last lecture closed. But his terminology enables us to summarize that theory by stating our own metaphysical thesis thus: "The universe consists of real Signs and of their interpretation."

In the order of real time the events of the world are signs. They are followed by interpreters, or by acts of interpretation which our own experience constantly exemplifies. For we live, as selves, by interpreting the events and the meaning of our experience. History consists of such interpretations.

These acts of interpretation are, in their turn, expressed, in the order of time, by new signs. The sequence of these signs and interpretations constitutes the history of the universe. Whatever our experience exemplifies, our metaphysical doctrine of signs generalizes, and applies to the world at large.

The world's experience is, from this point of view, not merely a flux. For, as Bergson rightly asserts, the world of any present moment of time is a summary of the results of all past experience. This view of Bergson's, however, is no mere intuition, but is itself an interpretation. Our own metaphysical thesis states in terms of interpretation what Bergson states as if it were a result of simple intuition.

Since any idea, and especially any antithesis or contrast of ideas, is, according to our metaphysical thesis, a sign which in the world finds its real interpretation, our metaphysical theory may be called a "doctrine of signs."

The title which I have given to this lecture serves to direct attention, through the use of a purely technical term, to the main issue. This issue is the one presented by the thesis that the very being of the universe consists in a process whereby the world is interpreted, – not indeed in its wholeness, at any one moment of time, but in and through an infinite series of acts of interpretation. This infinite series constitutes the temporal order of the world with all its complexities. The temporal order is an order of purposes and of deeds, simply because it is of the essence of every rational deed to be an effort to interpret a past life to a future life; while every act of interpretation aims to introduce unity into life, by mediating between mutually contrasting or estranged ideas, minds, and purposes. If we consider the temporal world in its wholeness, it constitutes in itself an infinitely complex Sign. This sign is, as a whole, interpreted to an experience which itself includes a synoptic survey of the whole of time. Such is a mere sketch of our doctrine of the world of interpretation.

III

I may aid towards a further understanding of our metaphysical thesis by using, at this point, an illustration.

When you observe, at a crossing of roads, a sign-post, you will never discover what the real sign-post is, either by continuing to perceive it, or by merely conceiving its structure or its relations to any perceived objects, or to any merely abstract laws in heaven or in earth. Nor can you learn what the signpost is by any process of watching in the course of your individual experience the "workings" of any ideas that it suggests to you as this individual man. You can understand what the sign-post is only if you learn to read it. For its very being as a sign-post consists in its nature as a guide, needing interpretation, and pointing the way. To know the real sign-post, you must then learn to interpret it to a possible hearer to whom you address your interpretation. This being to whom you address your interpretation must be a self distinct from your individual self. If, then, the sign-post is a sign-post at all, there are beings in the world that are neither individual objects of perception nor yet beings such that they are mere universals, the proper objects for conception.

If the sign-post is a real sign-post, there is in the world a community constituted of at least three distinct minds. There is, first, the mind whose intention to point out the way is expressed in the construction of this sign-post. There is the mind to which the sign-post actually points out the way. But the sign-post does not effectively point out the way to anybody unless, either by the aid of his own individual memory, or of somebody who helps him to read the sign, he learns what the sign means. There must then be a third mind which interprets the sign-post to the inquiring wayfarer. The wayfarer, if he knows how to read, may be his own interpreter. But there remain the three distinct mental functions. There is the function of the mind whose purpose the sign expresses; there is the mind which is guided by the interpretation of the sign; and there is the function of the interpreter to whom the reading of the sign is due. All these minds or functions must be real and distinct and must form one real community, if indeed the sign-post is a real sign-post at all.

This illustration may help us to grasp what the first thesis of our metaphysical doctrine means. Our experience, as it comes to us, is a realm of Signs. That is, the facts of experience resemble sign-posts. You can never exhaustively find out what they are by resorting either to perception or to conception. Nor can you define experience merely in terms of the sort of knowledge which pragmatism emphasizes. No "working" of any single idea can show what a real fact of experience is. For a fact of experience, as you actually view that fact, is first an event belonging to an order of time, – an event preceded by an infinite series of facts whose meaning it summarizes, and leading to an infinite series of coming events, into whose meaning it is yet to enter. But the past and future of our real experience are objects neither of pure perception nor of pure conception. Nor can you, at any present moment, verify any present idea of yours about any past event. Nor can you define past and future in terms of the present workings of any ideas. Past time and

future time are known solely through interpretations. Fast time we regard as real, because we view our memories as signs which need and possess their interpretations. Our expectations are interpreted to our future selves by our present deeds. Therefore we regard our expectations as signs of a future.

Therefore, to a being who merely perceived and conceived, or who lived wholly in the present workings of his ideas, past time and future time would be as meaningless as the sign-post would be to the wayfarer who could not read, and who found nobody to interpret to him its meaning. If the past and future are realities, then they constitute a life which belongs to some real community, whose ideas of past and of future are really interpreted.

Now our doctrine of the world of interpretation extends to all reality the presuppositions which we use in all our dealings with past and future time. Our memories are signs of the past; our expectations are signs of the future. Past and future are real in so far as these signs have their real interpretation. Our metaphysical thesis generalizes the rules which constantly guide our daily interpretations of life. All contrasts of ideas, all varieties of experience, all the problems which finite experience possesses, are signs. The real world contains (so our thesis asserts) the interpreter of these signs, and the very being of the world consists in the truth of the interpretation which, in the whole realm of experience, these signs obtain.

Let us turn back from these technical formulations and from these illustrations, and come again closer to the real life for which they are intended to stand.

IV

Despite my frequent mention of differences, there is one respect in which I am in full agreement with the spirit of pragmatism, as James defined it. Any metaphysical thesis, if it has a meaning at all, is the expression of an attitude of the will of the one who asserts this thesis.

In a remarkable recent book, entitled: "Die Philosophie des Als Ob," Vaihinger has given his own formulation to a view which he originally reached independently of the influence of pragmatism. It is the view that a philosophy is, in its essence, a resolution to treat the real world as if that world possessed certain characters, and as if our experience enabled us to verify these characters. This resolution is, in its essence, an active attitude of the will. Therefore Voluntarism must form an essential part of every philosophy which justly interprets our metaphysical interests. For our metaphysical interests are indeed interests in directing our will, in defining our attitude towards the universe, in making articulate and practical our ideals and our resolutions. So far, I say, Vaihinger and the pragmatists are right.

I do not believe, however, that our voluntarism must remain a *mere* pragmatism. I have long defended a philosophy, both of human life and of

the universe, which I have preferred to call an "Absolute Voluntarism." I developed such a philosophy, partly under the influence of James, but long before recent pragmatism was in question. In its most general form, this philosophy to which I myself adhere, asserts that, while every metaphysical theory is the expression of an attitude of the will, there is one, and but one, general and decisive attitude of the will which is the right attitude, when we stand in presence of the universe, and when we undertake to choose how we propose to bear ourselves towards the world. Any philosophy is inevitably a doctrine which counsels us to bear ourselves towards our world *as if* our experience were such and such. But I do not believe that the "Philosophy of the 'As if'" is, as Vaihinger asserts, merely a system of more or less convenient fictions. For if there are absolute standards for the will (and, in my own opinion, there are such standards), then the world of the will is no world of fictions. If there is one, and but one, right attitude of the will towards the universe, this attitude, when once assumed, is essentially creative of its own realm of deeds. Its so-called fictions are, therefore, not mere fictions, for they constitute a real life. Its so-called successes are no merely transient successes. For if there is any true success at all, every such success, however petty it seems, has a world-wide meaning. The realm of true success is not merely a world of change. For deeds once done are irrevocable; and every deed echoes throughout the universe. The past is unchanging. The expression of the will constitutes itself an actual life. The creative activity of the will is therefore no mere play with figments. It has the reality of a realm of deeds. And every deed has a value that extends throughout the world of the will. Each act is to be judged in the light of the principle: "Inasmuch as ye have done it unto the least of these."

I do not wish here to dwell upon the general features which I have repeatedly ascribed to this world of the will, where every fact is the expression of an individual decision, and is therefore an absolute fact. I do not intend to repeat even the outlines of my former statements, both of this absolute voluntarism and of my own type of idealism. I have too often told that tale. So far as possible, I wish, in the present exposition, to speak as if all my former words were unspoken.

As a fact, I still hold by all the essential features of these former attempts to state the case for idealism. But at present I am dealing with the World of Interpretation, and with the metaphysics of the Community. This I believe to be simply a new mode of approach to the very problems which I have formerly discussed.

My present interest lies in applying the spirit of my absolute voluntarism to the new problems which our empirical study of the Christian ideas, and our metaphysical theory of interpretation, have presented for our scrutiny.

With this, then, as the end now in view, let me try to tell you what attitude of will, what practical bearing towards the universe, what resolution, what

plan of life, should characterize, in my opinion, any one who undertakes to view the world in the light of that doctrine concerning the nature and the business of interpretation, which, at the last time, I sketched.

This essentially social universe, this community which we have now declared to be real, and to be, in fact, the sole and supreme reality, – the Absolute, – what does it call upon a reasonable being to do? What kind of salvation does it offer to him? What interest does it possess for his will? If he accepts such a view of things, how should he bear himself towards the problem of life? To what ideas of his own does such a view offer success? How can he bring such a view into closer relations with ordinary human experience?

V

James declared that the typical pragmatist is a man of an essentially dramatic temper of mind. I now have to point out that the believer in our world of interpretation also centers his interests about a genuinely dramatic undertaking.

I have already said that the world of interpretation includes an infinite series of acts of interpretation. I have shown, in an earlier lecture, that every act of interpretation involves novelty. The believer in this doctrine of signs, the one to whom every problem, every antithesis, every expression of mind, every tragedy of life, is a sign calling for interpretation, and in whose belief the world contains its own interpreter, both contemplates and shares in a world drama. But the attitude of will which befits one who holds this doctrine of signs can only be rightly understood in case we first distinguish three very general attitudes of the will with which, in certain of their special forms, we have now become well acquainted. Our will is always dramatic in its expressions. It passes from deed to deed. Its world is a world of sequences and of enterprises. But when it surveys this world, and when it summarizes the spirit of its undertakings, the will may assume any one of three distinct modes of appreciating both itself and its realm of actual or of possible deeds.

VI

The first of these modes, the first of the attitudes of the will to which I here direct your attention, is that to which Schopenhauer gave the name, "The Affirmation of the Will to live." This phrase of Schopenhauer is intended by its author to be extremely general, and to apply to active dispositions which are exemplified by all sorts and conditions of men. Whatever the natural man seeks, he intends, says Schopenhauer, to live if he can. And when the natural man affirms this will to live, he may have in mind any one of countless different, or even conflicting, motives and purposes.

He may be seeking pleasure, wealth, power, praise, material possessions, or manifold spiritual goods. He may call it righteousness or food, that he

desires. It may be the destruction of his enemies or the prosperity of his friends that he has in mind when he sets out towards his goal. He may be of any calling that you please. He may be a worldling or a recluse; a beggar or a king; an outcast or the center of an admiring company. In brief, his special purposes may vary as you will. The ideas, the "leadings," which, in the pragmatic sense, he desires to have succeed, may vary from man to man and from life to life, throughout the whole range of our social and individual objects of desire.

But, in any case, if, in Schopenhauer's sense, such a man affirms the will to live, be essentially desires to be himself, whoever he may be, and to win his aims, whatever the special aims be to which he commits himself. This desire for self-assertion, then, is present in all the Protean shapes of the affirmation of the will to live, and vivifies them.

While one affirms the will to live, he therefore gives himself over to the great game of life. As an individual man he has his friends and his enemies; his triumphs and defeats; his joys and his sorrows of pain and grief. But what happens to him does not, in so far, touch the heart and core of his will. He may shout with triumph, or cry aloud in his woe; he may pray to his gods for help, or may curse his fate in what he calls his despair; but withal, he means to continue his pursuit of the objects of desire. He may repent of his sins; but not of being himself. He may, in his hatred of ill-fortune, resort even to suicide. But such suicide is merely a revolt against disaster. It only affirms in its own passionate way the longing for some life which is not indeed the present life of the rebel who seeks suicide, but which, in all his condemnation of his own deeds or of his own misadventures, he still longs to live, if only death and the universe will yet permit him to express himself.

VII

Schopenhauer usually emphasizes the essentially selfish nature of this will to live, as it inspires the individual man. Yet Schopenhauer fully recognizes that we are all social beings, and that the will to live can keep us eagerly busy in and with the world of our fellows. Only, as Schopenhauer rightly interprets this affirmation of the will to live, the recognition of his fellow-men which the victim of this will to live constantly makes, is based, so to speak, upon the natural solipsism of the individual will.

And here we come to the very root, the inmost meaning, of this first of the three attitudes of the will which we are here considering.

One who thus, in Schopenhauer's sense, affirms the will to live, may cheerfully and sincerely acknowledge that other men exist, and he may be a good member of society. But he tends to found this acknowledgment of his fellow-man, and of the social will, upon what most philosophers regard as an argument from analogy. A man may, by reason of such analogy, extend the realm to which his will to live applies its interests. The early and purely

natural forms of family loyalty and of clan loyalty depend upon such practical expansions of the self. But, as we saw when we studied the Pauline doctrine of original sin, the will to live constantly meets its opponent in the wills of other individuals. And then its primal solipsism revives; and it hates its fellows. And even when such a will recognizes that an organized social will is in some sense a reality, it finds this social will either as a foreign fact, or as a mystery.

In brief, all the social facts seem to a man in whom Schopenhauer's will to live finds its natural affirmation, external and in general problematic, – known only through analogy and doubtfully. I will my own life; and observe my own life. My dealings with you seem, from this point of view, to be due to motives external to this will of mine.

"Why," says Professor James, addressing a supposed fellow-man in one of his essays on Radical Empiricism, "Why do I postulate your mind? Because I see your body acting in a certain way. Its, gestures, facial movements, words, and conduct generally are 'expressive,' so I deem it actuated, as my own is, by an inner life like mine. This argument from analogy is my *reason*, whether an instinctive belief runs before it or not. But what is 'your body' here but a percept in *my* field? It is only as animating *that* object, *my* object, that I have any occasion to think of you at all."

In the form of this familiar argument from analogy, – an argument which many philosophers indeed regard as expressing our principal reason for believing that our neighbors' minds are realities, – James also puts into words an equally familiar aspect of the metaphysical view which naturally accompanies this affirmation of the will to live. I perceive my own inner life, or, at all events, my own facts of perception. By analogy I extend the world thus primarily known to me. Other men are, in this way, hypothetical extensions of myself. For the rest, I believe in them because, unless I take due account of them, they snub or thwart my own will to live. My ideas are my own, and it is of the essence of my life as this individual that I want my own ideas to "work." Upon this affirmation of my will to live depends all the truth that I shall ever come to know.

Pragmatism, in its recent forms, is indeed one of the most effective philosophical expressions which Schopenhauer's "Will to live" has ever received. Pragmatism is fond of insisting upon its cordial and unquestionably sincere recognition both of the social world and of the real existence of many selves, and of countless distinct ideas.

But as a fact, this recognition of the many selves, of the real world, and of the infinite variety of ways in which different ideas obtain now one and now another "working," – this entire view of truth and of reality, – when pragmatism deals with such matters, is founded upon the view that (as James loved to say) all "workings" are "particular." Each idea aims at accomplishing the event which, if reached, then and there constitutes the truth of that

particular idea. Each idea therefore expresses and, as far as it can, affirms its own will to live. Each idea aims at its own success. Ideas, like all the other facts of James's world, hang together, as James was accustomed to say, "by the edges," if indeed they hang together at all. Their unities are temporary, accidental, and nonessential. The world of truth is thus indeed a dramatic world where each idea asserts itself while it can.

The life of truth is a drama wherein each pragmatic "leading," each individual expression of the will to succeed, "struts and frets its hour upon the stage, and then is heard no more."

Such is the philosophy wherein Schopenhauer's affirmation of the will to live finds its most recent, and, on the whole, as I suppose, its most effective expression.

VIII

In strong contrast to the affirmation of the will to live, Schopenhauer placed that attitude which he defined as the resignation, – the denial of the will to live. Here we have to deal with a tendency too well known to all students of the history of the spiritual life to need, in this place, extended portrayal, and too simple in its fascinating contrast with our natural life to require minute analysis. This is the attitude of the will which Southern Buddhism taught as the sole and sufficient way of salvation. In the form of saintly resignation the same ideal has received countless Christian expressions. Repeatedly this form of self-denial has been supposed to constitute the essence of Christianity. Repeatedly the expounders and defenders of the Christian doctrine of life have been obliged to insist that the Christian form of salvation does *not* consist in this simple abandonment of the will to live. I will not here repeat the tale which the greatest work of Christianity throughout the ages has so freely illustrated. Resignation alone does not save. To abandon his will to live does not by itself enable the individual to win the true goal of life. Let us, for the moment, simply accept this fact.

But since we are here interested in the metaphysical relations of these attitudes of the will, let us mention, in passing, that the resignation of the will to live is an attitude to which there correspond appropriate forms of metaphysical opinion. Here, again, the connections are well known, and need not here be dwelt upon. It is enough to say that whoever abandons the will to live, ceases, of course, to be interested in those "workings" of ideas which pragmatism regards as bringing us into empirical and momentary touch with the real. To such a resigned will, there remain only the cognitive processes of pure conception and of pure perception to consider. On the whole, in the history of thought those for whom salvation consists in the denial of the will to live have resorted to the metaphysics of pure perception, and have been mystics.

As has now been repeatedly pointed out by his critics, Bergson's philosophy consists of two parts, – a pragmatism which he regards as always incomplete and unsatisfactory, and a mysticism which, as he more fully expresses himself, be tends to make more prominent. The corresponding attitudes of the will also play their part, both in Bergson's cosmology and in his metaphysics. On the whole, Bergson thus far emphasizes the joyous aspect of his own philosophy of life. But plainly, in his view, the evolutionary process has been dominated by the will to live. And the inevitable outcome of such a domination, so long as the will to live takes the form which Schopenhauer and Bergson ascribe to it, is the discovery that such a realm of mere vital impulse is vanity, and vexation of spirit. Whenever the mysticism of Bergson is fully developed, by himself or by his followers, there will come to be expressed the corresponding attitude of the will. The vital impulse will be transformed into resignation; as Bergson's insistence upon free activity has already been subordinated to his counsel that we should give ourselves over to mere perception. When he tells us that the true artist perceives "for the sake of nothing, for the mere pleasure of perceiving," we remember Schopenhauer's saint, for whom "This our so real world, with all its suns and its milky ways," became "Nothing." Such, in fact, is the end of the mystic.

IX

But there is indeed a third attitude of the will. It is not Schopenhauer's attitude of the affirmation of the will to live. It is also not the other attitude which Schopenhauer believed to be the sole and sufficient salvation of the will. And this third attitude of the will possesses its appropriate metaphysics. As for what this attitude of the will is, – when we consider, not its doctrine of the universe, but its doctrine of life, – we are already well acquainted with it, because our entire discussion of the Christian ideas was devoted to making us familiar with its moral and its religious meaning. In returning, at this point, to the mention of this attitude of the will, I do so because we now are ready to understand the relation between this type of will, and the metaphysical doctrine of which I believe it to be the fitting accompaniment. Whoever has learned to understand the meaning of this third way in which the will can bear itself towards its world, will therefore be better prepared to grasp the foundations upon which the metaphysics of interpretation rests. The human value of this practical attitude does not by itself fully reveal the grounds of the technical theory which is here in question. But the intimate relations between theory and life are nowhere more pronounced than in this case, where reason and sentiment, action and expression, throw light, each upon the other, as is hardly anywhere else the case.

The attitude of the will which Paul found to be saving in its power, just as, to his mind, it was also divine in its origin, was the attitude of Loyalty. Now

loyalty, when considered from within, and with respect to its deepest spirit, is not the affirmation of the will to live of which Schopenhauer spoke. And loyalty is also not the denial of the will to live. It is a positive devotion of the Self to its cause, – a devotion as vigorous, as self-asserting, as articulate, as strenuous, as Paul's life and counsels always remained. The apostle himself was no resigned person. His sacrifices for his cause were constant, and were eloquently portrayed in his own burning words. They included the giving of whatever he possessed. But they never included the negation of the will, the plucking out of the root of all desire, in which Gotama Buddha found salvation. Paul died at his conversion; but only in order that henceforth the life of the spirit should live in him and through him.

X

Now this third attitude of the will, as we found in dealing with the whole Christian doctrine of life, has in any case its disposition to imagine, and also practically to acknowledge as real, a spiritual realm, – an universal and divine community. Christian theology, in its traditional forms, was a natural outcome of the effort to define the world wherein the loyal will can find both its expression and its opportunity. We have not now to consider the religious aspect of this third attitude of the will. But we are now fully prepared to state its relation to the metaphysical problems. All the threads are in our hands. We have only to weave them into a single knot.

As a reasonable being, when once I have come to realize the meaning of my dealings both with life and with the world, the first practical principle, as well as the first theoretical presupposition of my philosophy must be this: Whatever my purposes or my ideas, – whatever will to live incites me to create and to believe, whatever reverses of fortune drive me back upon my own poor powers, whatever problems baffle me, through their complexity and my ignorance, one truth stands out clear: Practically I cannot be saved alone; theoretically speaking, I cannot find or even define the truth in terms of my individual experience, without taking account of my relation to the community of those who know. This community, then, is real whatever is real. And in that community my life is interpreted. When viewed as if I were alone, I, the individual, am not only doomed to failure, but I am lost in folly. The "workings" of my ideas are events whose significance I cannot even remotely estimate in terms of their momentary existence, or in terms of my individual successes. My life means nothing, either theoretically or practically, unless I am a member of a community. I win no success worth having, unless it is also the success of the community to which I essentially and by virtue of my real relations to the whole universe, belong. My deeds are not done at all, unless they are indeed done for all time, and are irrevocable. The particular fortunes upon which James lays so much stress are not even particular, unless

they consist of individual events which either occur or do not occur. Each of these real events has therefore a being which lasts to the end of time, and a value which concerns the whole universe.

Such, I say, is the principle, at once theoretical and practical, upon which my philosophy must depend. This principle does not itself depend upon the momentary success of any individual idea. For it is a principle in terms of which we are able to define whatever real life there is, while, unless this principle itself holds true, there is no real life or real world in which we can find success.

XI

Now this principle is one which, with various dialectical explanations, I have, in other essays of my own, repeatedly defended. And, as I have said, I have no wish whatever to repeat, in this context, my own previous discussions. The relation of this essentially social attitude of the decisive will to the doctrine of the community, leads me to show what this general and underlying attitude of the social will is, by mentioning, as I pass, and by way of illustration, that most familiar and most profoundly metaphysical of the problems of common sense, the problem: What reason can any one of us give for holding that the mind of his neighbor is real at all? For the attitude of will, the postulate, the resolution which any one of us takes when he says to his fellow, "You are a real being," is precisely that attitude which our metaphysical thesis advises us to take towards the whole world when it tells us to say to the world: "I know that you are real, because my life needs and finds its interpreter. You, O World, are the interpretation of my existence."

At all events, the case of the bases of our ordinary social knowledge is a test case deciding the whole attitude towards life and towards truth and towards the universe.

XII

For James, as you have already seen, my only and, to his mind, my sufficient ground for believing in my fellow's existence, for "postulating your mind," is an argument from analogy, an extension of the inner life of my already known self, with its feelings, with its will, and with the workings of its ideas, into the perceived body of my neighbor, whose movements and expressions resemble mine.

Now, as a fact, the most important part of my knowledge about myself is based upon knowledge that I have derived from the community to which I belong. In particular, my knowledge about the socially expressive movements of my own organism is largely derived from what I learn through the testimony of my fellow-men. Therefore I cannot use the analogy of our exter-

nally expressive movements as my principal reason for believing in the reality of the inner life of my fellow-man, because I am very largely unable to perceive my own expressive movements in as direct a way as is that in which I perceive the organism and the movements of my fellow-man.

For instance, the appearance of my fellow's countenance is to me a sign of his mind. And signs of this type stand in the front rank of those facts of perception upon which my customary interpretation of his mind depends whenever he and I are in each other's presence.

But is my main argument for the thesis that my fellow's face expresses his mind, – and that his facial expressions are evidences of the existence of his mind, – an argument from analogy? Do I reason thus: "When my face looks thus, I feel so and so; therefore, since my neighbor's face looks thus, it is fair to reason by analogy that he feels so and so?" How utterly foreign to our social common sense would be this particular argument from analogy!

For, as a fact, I know very little about my own facial expressions, except what I learn, if indeed I learn it at all, through accepting as true certain reports of my neighbors regarding these facial expressions. I can indeed indirectly perceive my own face by looking in the mirror. But I thus learn hardly anything of importance to me about what my own changes of facial expression are. I have spent years of my life interpreting the signs which I read as I look at the countenances of other men. But when have I said to my neighbor: "Come, let us look in the glass together, so that, observing how my facial expression varies with my state of mind, I can learn to judge by the analogy of my own countenance what your changes of countenance probably mean?" To "postulate your mind" upon such a basis would be a form of solemn fooling.

The case is trivial, but typical for the way in which we interpret the usual signs of his mind which our neighbor gives to us. In large part, since I never normally view my own organism in a perspective which is closely analogous to the perspective in which I constantly perceive the body and the movements of my fellow-man. My most important knowledge about my own expressive movements comes to me at second hand. I learn how my own movements appear through the report of others.

Thus, then, I first believe that my fellow has a mind. As part or as consequence of this belief, I accept his testimony about how the movements of my organism seem when they are perceived by another man. As a result, I learn indirectly, and by the circuitous route that, so to speak, passes through my neighbor's mind, precisely the most significant of the analogies between my neighbor's expressive movements and my own. Yet these analogies are supposed, by James, and by the prevalent theory, to constitute my main evidence that my neighbor has a mind at all!

It would be hard to mention an instance of a more artificial doctrine than this prevailing opinion of philosophers regarding the bases of our social

consciousness. Yet this is the very doctrine which James advances as a typical illustration of his own radical empiricism. What I, as an individual, never experience at all, – namely, precisely those analogies between my own doings and my neighbor's outward behavior which are socially most important, are named by James as furnishing my sole reason for "postulating your mind."

XIII

Why, then, do I indeed postulate your mind?

I postulate your mind, first, because, when you address me, by word or by gesture, you arouse in me ideas which, by virtue of their contrast with my ideas, and by virtue of their novelty and their unexpectedness, I know to be not any ideas of my own.

Hereupon I first try, however I can, to interpret these ideas which are not mine. In case you are in fact the source of these new ideas of mine, I fail to find any success in my efforts to interpret these ideas as past ideas of my own which I had forgotten, or as inventions of my own, or as otherwise belonging to the internal realm which I have already learned to interpret as the realm of the self.

Hereupon I make one hypothesis. It is, in its substance, the fundamental hypothesis of all our social life. It is the hypothesis that these new ideas which your words and deeds have suggested to me actually possess an interpretation. They have an interpreter. They are interpreted. This hypothesis simply means that there exists some idea or train of ideas, which, if it were now present within my own train of consciousness, would interpret what I now cannot interpret. This interpreter would mediate between the new ideas which your deeds have suggested to me, and the trains of ideas which I already call my own. That is, this interpreter, if he fully did his work, would compare all these ideas, and would both observe and express wherein lay their contrast and its meaning. My hypothesis is that such an interpreter of the novel ideas which your expressive acts have aroused in me, actually exists.

Now such an interpreter, mediating between two contrasting ideas or sets of ideas, and making clear their contrasts, their meaning, and their mutual relations, would be, by hypothesis, a mind. It would not be my own present mind; for by myself alone I actually fail to interpret the ideas which your deeds have aroused in me. And these ideas which your doings have aroused in me are simply not my own. Now this hypothetical interpreter is what I mean by your self, precisely in so far as I suppose you to be now communicating your own ideas to me. You are the real interpreter of the ideas which your deeds suggest to me. That is what I mean by your existence as an "eject."

The reason, then, for "postulating your mind" is that the ideas which your words and movements have aroused within me are not my own ideas, and cannot be interpreted in terms of my own ideas, while I actually hold, as

the fundamental hypothesis of my social consciousness, that all contrasts of ideas have a real interpretation and are interpreted.

XIV

Our illustration has carried us at once into the mazes of our problematic social life together. But the case is a typical case. We have but to view it in its principle, and it shows what attitude of the will is the only decisive one in dealing with the interpretation of experience.

You are not a mere extension by analogy of my own will to live. I do not, for the sake merely of such analogy, vivify your perceived organism. *You are an example of the principle whose active recognition lies at the basis of my only reasonable view of the universe. As I treat you, so ought I to deal with the universe. As I interpret the universe, so, too, in principle, should I interpret you.*

We have no ground whatever for believing that there is any real world except the ground furnished by our experience, and by the fact that, in addition to our perceptions and our conceptions, we have problems upon our hands which need interpretation. Our fundamental postulate is: *The world is the interpretation of the problems which it presents.* If you deny this principle, you do so only by presenting, as Bergson does, some other interpretation as the true one. But thus you simply reaffirm the principle that the world has an interpreter.

Using this principle, in your ordinary social life, you postulate your fellow-man as the interpreter of the ideas which he awakens in your mind, and which are not your own ideas. The same principle, applied to our social experience of the physical world, determines our ordinary interpretations of nature and guides our natural science. For, as we have seen, the physical world is an object known to the community, and through interpretation. The same principle, applied to our memories and to our expectations, gives us our view of the world of time, with all its infinite wealth of successive acts of interpretation.

In all these special instances, the application of this principle defines for us some form or grade of community, and teaches us wherein lies the true nature, the form, the real unity, and the essential life of this community.

Our Doctrine of Signs extends to the whole world the same fundamental principle. The World is the Community. The world contains its own interpreter. Its processes are infinite in their temporal varieties. But their interpreter, the spirit of this universal community, – never absorbing varieties or permitting them to blend, – compares and, through a real life, interprets them all.

The attitude of will which this principle expresses, is neither that of the affirmation nor that of the denial of what Schopenhauer meant by the will to live.

It is the attitude which first expresses itself by saying "Alone I am lost, and am worse than nothing. I need a counsellor, I need my community. Interpret me. Let me join in this interpretation. Let there be the community. This alone is life. This alone is salvation. This alone is real." This is at once an attitude of the will and an assertion whose denial refutes itself. For if there is no interpreter, there is no interpretation. And if there is no interpretation, there is no world whatever.

In its daily form as the principle of our social common sense, this attitude of the will inspires whatever is reasonable about our worldly business and our scientific inquiry. For all such business and inquiry are in and for and of the community, or else are vanity.

In its highest form, this attitude of the will was the one which Paul knew as Charity, and as the life in and through the spirit of the Community.

Such, then, is the relation of the Christian will to the real world.

SOME PSYCHOLOGICAL PROBLEMS EMPHASIZED BY PRAGMATISM

Josiah Royce. "Some Psychological Problems Emphasized by Pragmatism." *Popular Science Monthly* 83.10 (October 1913): 394–411.

It is not my purpose upon this occasion to enter into the philosophical aspect of the discussion regarding pragmatism, excepting in so far as may be necessary to call attention to the psychological problems that I now have in mind. I presuppose, of course, a familiarity on the part of all of you with the main outlines of the recent discussions concerning the problem of truth. But I shall not try with any exactness to define what the term pragmatism means. I recognize that the word as now used refers to a considerable variety of opinions, and that the comparison of a "holding company" which Professor Dewey has, I believe, on one occasion employed, is not altogether inapt. It is enough for our present purpose that by the name pragmatism we all of us mean a certain set of tendencies in recent discussion which lay stress upon the importance of defining the truth of propositions or judgments or ideas in terms of those empirical facts and relations of facts which are said to constitute the "workings" of the propositions, or judgments, or ideas which are in question. The favorite summary of pragmatism, to the effect that from the point of view of pragmatism a proposition, or judgment, or idea is true "if it works," is sufficient to serve as a general indication of the tendencies of opinion which are here in question.

What pragmatism asserts about truth may be considered from the point of view of a general theory of knowledge, or of a metaphysic. But pragmatism itself especially emphasizes its relation to psychology, on the one hand, and to the recognized methods of empirical science, on the other. As Mr. Schiller said to me during the Philosophical Congress of 1908 at Heidelberg, "What is most essential to pragmatism is that it insists that the relations and values of the thinking process must be estimated in psychological terms. Success tests truth, and success is itself a matter of experience that can best be understood when it is defined psychologically." Another way of stating the essence of pragmatism is to insist, as Professor Dewey has so often done, upon the fact that the method which pragmatism proposes to apply to all problems is the method already used by the various sciences of experience. They employ "working hypotheses." They test these working hypotheses by comparison

with experience. Pragmatism consists in the assertion that all propositions should be tested as the hypotheses of science are tested.

These two points of view are, of course, very closely connected. Students of the physical sciences often take little account of the psychology of their own processes. But the processes of science obviously have their psychology, and this psychology conforms in its types to those laws of mental activity which have interested psychologists ever since the apperceptive process was formulated by Herbart, – yes, ever since the doctrine of association was so widely applied by the English psychologists, and still more since the modern so-called "functional" psychology has connected the apperceptive processes and the associative linkages with the physical processes whereby an organism is adjusted to its environment. The psychology of the apperceptive process, and the work of the scientific finding and testing of hypotheses, have a close relation, and since common sense also is interested in successful verifications, although this interest is less precise than is the interest of the student of the more exact sciences of observation in the criteria to which they submit their more careful tests, – common sense and science and psychology join in contributing their various shares to the modern general theory of truth.

But now to come to the matter to which I wish especially to attract your attention. Since pragmatism is thus especially interested in the psychology of the thinking process, it has emphasized this psychological problem in recent literature. A general psychology of thought, on a pragmatic basis, has been worked out by Professor Pillsbury. The psychological text-books of the Chicago school, and in particular the contributions of Professor Dewey, have familiarized us with other accounts of the psychology of thought. The psychological problems to which attention is thus especially attracted may be, of course, studied apart from their relations to the theory of truth. These problems are threefold. (1) There are the problems regarding the processes whereby hypotheses are invented, or, in common-sense terms, the processes whereby people get their ideas; (2) there are problems regarding the processes whereby ideas, once in hand, are made sufficiently clear to be a proper subject for testing; and (3) a psychological problem arises as to what happens when an idea is tested. To all these problems the pragmatists as psychologists have contributed. I wish to illustrate in the course of my discussion a certain dissatisfaction which I feel with the present state of some of their contributions to these purely psychological issues, when viewed apart from the other issues of the pragmatist philosophy.

Yet I admit that when you hear me you will say that my psychological dissatisfactions are due to certain philosophical dissatisfactions, and that the pragmatist psychology appears to me inadequate partly because I do not wholly accept the pragmatist theory of truth. I recognize the connection in my own mind between the two dissatisfactions. I do not wish to pretend that I can wholly dissociate my interest in psychology from my interest in the other

aspects of the pragmatist controversy and in the very nature of pragmatism itself. My pragmatist friends least of all would desire me to do this. And so I shall aid you in following my further inquiries if I first briefly state one ground of my dissatisfaction as a student of logic and of general philosophy, with the pragmatist's theory of truth. This statement I make not as if it were here important for the psychological purpose of this discussion, but because by confessing my own state of mind I may help you to fix your attention upon matters that will more directly interest you. For my dissatisfaction as a student of logic, with the pragmatist theory regarding truth, will call attention to the way in which I should approach precisely those psychological problems which pragmatism has most emphasized.

I

When pragmatism asserts that the truth of a proposition is tested by the "workings" of the ideas that the proposition expresses, a student of logic very naturally raises the question as to *what* workings are meant. A man who hears a proposition and who more or less completely understands its meaning, and who hereupon more or less believes the proposition, has certain mental attitudes aroused in him, and these mental attitudes have their physical expression. They tend to lead to action. The action may well be accompanied by expectations of various sorts, and the expectations may remain throughout more or less identical with those that the utterance of the proposition first arouses in the mind of the inquirer. Thus ideas may lead to actions. These actions may gratify or in a measure satisfy expectations. In this case the ideas which the proposition expressed are said to "work." But now consider the contrast between what this decidedly general statement expresses and what a student of any more exact empirical science is likely to have in mind when he thinks of testing the truth of a definite assertion. One familiar process of testing the truth of hypotheses in scientific regions is to trace the consequences that must be true if those hypotheses are true, and then to see whether these consequences can be found verified by particular experiences. An essential part of this process is the deduction of certain consequences from one's hypothesis. How extensive this deductive process may be, a glance at any textbook of theoretical physics, in particular of theoretical astronomy of the classic type, will show.

Now what happens when one deduces the consequences of an hypothesis? Does one simply let one's ideas work? Are the consequences of hypotheses simply ideas that are as a fact aroused in the mind of a man who begins with the hypothesis itself in mind? Certainly the usual taste and purpose of the student of any more exact science is *not* sufficiently expressed by saying that he looks merely for such "workings" as may happen to be suggested to his mind. *He is looking for what must be true if the hypothesis is true.* He is

making use of those mental processes whose nature is sometimes discussed in text-books of deductive logic. But when we are dealing merely with the world of common sense, ideas that have been suggested or propositions that have been uttered, frequently arouse in our minds expectations which are not directly called for by the logical meaning of the propositions, but which through various processes of association or various reminders of past experience are more or less casually aroused. Such resulting expectations may be said in a given mind to follow from the utterance of the proposition that arouses them. But they are not logical consequences of the proposition in the sense which the student of the more exact sciences has in mind.

Again, when the student of an exact science has made his deductions and proceeds to verify them, he may find his hypothesis confirmed or refuted by the results of experience. In this case his hypothesis may be said to "work," but what sort of working is in question in the more exact sciences? I answer, in any more exact science the confirmations or refutations which experience is able to furnish to the hypothesis whose logical consequences are to be tested, are required to be so exact that we can define them in definite *affirmations* and *denials*. The very essence of precise confirmation or refutation is that if it is as successful as the requirements of an exact science demand, we are able to say as the result of our process of confirmation, "So and so, thus and thus defined, happens or does not happen, is found or is not found." Or again, we sometimes say of the failing hypothesis, "It is *contradicted* by the facts." Somewhat different however is the situation in the world of common sense, where one's expectation may often be met or disappointed with very various degrees of definiteness. In the world of common sense a man may say, "This more or less meets my expectations." In the world of an exact science the investigator is interested in seeing within what precise limits a definite experienced measurement agrees with the prediction. *Precision*, in other words, characterizes the confirmations or refutations which experience furnishes in the more advanced sciences. And the concept of precision has characters which are studied in text-books of logic, although, as I admit, in most textbooks of logic the concept of precision is very inadequately studied.

In consequence of all this the student of logic is likely to object to the ordinary formulation of pragmatism, (1) that pragmatism seems not to be interested in the distinction between merely arousing an expectation, and deducing a consequence; (2) that it takes comparatively little account of the distinction between feeling more or less personal satisfaction in partial agreements between experience and our expectations, and precisely confirming or refuting a determinate hypothesis, in so far as that can be done by a certain group of experiences.

And finally the student of logic finds a certain difficulty in the usual statements of pragmatism regarding the sense in which empirical verifications are said to lead to a certain "belief" that the ideas which we have been trying to

verify are true. In ordinary life beliefs exist in all sorts of vague degrees of intensity. But when the student of a science formulates his results, considerable stress is laid upon the assertion that, by virtue of a given group of confirmations, a hypothesis has received a somewhat determinate degree of what is called *objective probability*. Now into the theory of probability this is no place to go. But most of you who have dealt with statistical probabilities will admit that our subjective confidence is somewhat different in its nature from that objective or statistically estimated probability which most students of an inductive science prefer to be able to define if they can. The whole modern development of the theory of probability has been in the direction of separating the concept of objective probability from the concept of subjective belief or confidence. From the objective point of view a proposition has a certain probability *P* in case it belongs to the class of propositions of which in the long run a proportion *P* are true. The difficulty of defining such probability with genuine exactness is great, and the whole subject of probability is too complex to be here discussed, but the student of logic feels dissatisfied with the fact that his pragmatist brethren take little interest in defining the difference between the vague confidence which in the world of common sense confirmed expectations may arouse, and the scientific measure of probability in exact and relatively objective terms which the students of an inductive science are commonly seeking.

II

So much for my general statement of logical scruples concerning the adequacy of pragmatistic formulations. Into the merits of these logical scruples I have no wish to go on this occasion. I have stated them merely in order to formulate the problems of a psychological nature to which I wish to attract attention. Pragmatism has emphasized these problems, has undertaken to solve them, has contributed a great deal to their study, but in my opinion has failed to satisfy all the requirements that it might satisfy, just because it is not sufficiently interested in the very logical problems that I have just outlined. These logical problems, however, have their psychological aspects. If one does not deal with them in an exact fashion from the logical point of view, one is not likely to have one's attention attracted to their psychological complexity. On the other hand, if I can do anything to awaken your interest in the psychological character of these problems, perhaps I may indirectly help to awaken interest in their logical aspect.

Let me repeat the list of the problems to which I have called attention, emphasizing the sense in which each one of them is a psychological problem. I mention the fact that a science which is testing hypotheses *deduces the logical consequences of these hypotheses*. The process may be an extended one. W*hat is the psychology of deduction?* What happens when a process of

deduction takes place? In some respects this problem has indeed been repeatedly dealt with from the psychological point of view. I do not wish in the least to deny that the analyses of Professor Pillsbury and others have contributed to this problem, but just because these psychologists have been so little interested in the logic of the deductive process they have failed, in my opinion, to emphasize some of its most important psychological aspects. Yet their own discussions emphasize the need of such a psychology. Here lies the first of the problems to which I now call attention.

Secondly, the pragmatists in speaking of the working hypothesis have emphasized, as Professor Moore has recently done, the fact that the agreement of an assertion or idea with its expected workings constitutes the test of its truth so far as up to a certain point in our investigations we may happen to have gone. I have called attention to the difference between an expectation and an assertion or a denial. One goes to the play expecting amusement. At the end of the play, have his expectations been met or not? The question may be unanswerable in any definite way. The play was amusing, and yet perhaps not so very amusing, or not so amusing as one could have wished it to be. One goes away partially disappointed, partially pleased. One is not so disappointed but that one continues to go to plays over and over again. One is not so pleased that he expresses himself very enthusiastically. What ideas with regard to the amusing character of plays have been precisely tested, so long as one remains in this state of mind? On the other hand, through a deductive process the occurrence of an eclipse is precisely predicted. The eclipse is observed, its beginning is noted with an accuracy as great as the errors of observation permit. A precise assertion is made as to the agreement between the prediction and the observation. When the assertion has received its proper qualifications with regard to probable error and the rest, the assertion appears in the records as true or false. In this case an issue is met and something is tested, yes or no. I now ask, what is the psychology of assertion and denial, of the difference between yes and no? In what way does this difference, namely that between yes and no, differ from any other kind of difference? This problem I mention, without hoping in this paper to do more than mention it. I called attention to this psychological problem some years since in an address that I was permitted to give before the Psychological Association. I venture to emphasize this problem afresh and to declare that it is a problem which the whole pragmatist controversy has itself especially emphasized and has not yet adequately solved.

Again I have called attention to the difference between vaguely estimated confidence and objective probability. Here is a problem that once more presents psychological aspects. I shall have no time to discuss them upon this occasion. The psychology of probability is, however, to my mind one full of very interesting problems.

III

I have thus enumerated three of the psychological problems which to my mind are emphasized by the course of the pragmatistic discussion. That these problems come to my mind with a special force because of my logical interest, you see. It is now my purpose to appeal to you as psychologists or as students interested in the subject, to follow for a few moments some further characterization especially of the first of these psychological problems. I am dissatisfied in the recent discussions of the psychology of reasoning with what seems to be a failure to understand what takes place in exact deductive procedure. The current prejudices as well as the hoary traditions on this subject seem to conspire to call the attention of students away from the center of the problem. Without attempting to give any adequate summary of Professor Pillsbury's account of the reasoning process in his recent "Psychology of Reasoning," I may attempt by a few references to indicate how inadequate some current views are to take account of what the deductive process actually is. In Professor Pillsbury's "Psychology of Reasoning," he distinguishes pretty sharply between the two processes of *inference* and *proof*. By inference, if I understand him, he means the process whereby a conclusion is suggested in such wise as to arouse more or less belief. By proof he means a process whereby this belief is more or less adequately tested. Now logicians are accustomed to use the word inference in a somewhat different way from that which Professor Pillsbury emphasizes. And what this way is I shall try to point out in a moment. But laying inference aside for the moment, and passing to the other side of the reasoning process as Professor Pillsbury defines it, namely to the process of proof, the only form of deductive proof which Professor Pillsbury seems to emphasize is the one that has received its traditional description in the doctrine of the syllogism. The essence of the traditional syllogism is, according to Professor Pillsbury, that the general major premise is supposed to aid us in testing our belief in the conclusion, by virtue of the fact that in the minor premise something has been brought under this major premise as a particular case of the principle. Professor Pillsbury consequently points out how comparatively insignificant both from the logical and from the psychological point of view the syllogism is as an expression of the nature of the concrete process of reasoning. To bring cases under major premises is to do little to confirm our belief except in so far as one thus emphasizes in a somewhat formal way the tendency of every new or questionable fact to find its place by being brought into conformity with the habits, or better with the principles of action, which have been formulated on the basis of previous experience. Deductive proof appears therefore to be, as Professor Pillsbury says, not so different from induction as is usually supposed, and to be in any case of comparatively minor importance. The business of proof, according to Professor Pillsbury, is to produce belief. Belief in general

is not produced by formulating major premises. It is produced by a more complex process whose general nature he sets forth.

Other familiar discussions of the reasoning process, such as one finds in the text-books of recent pragmatists, agree with Professor Pillsbury in assuming that it is of the essence of deduction or of deductive proof to proceed from the general to the particular, and that the significance of deductive proof lies in the fact that one hereby formulates, often somewhat uselessly, the general process by which an adjustment to the environment in cases of initial doubt or difficulty is attained. Apart from these statements more characteristic of pragmatists, a wide-spread tradition, which unfortunately is supported by the older logical text-books themselves, maintains that it is of the essence of deductive reasoning to bring nothing out of the premises except what was already in them, so that the essence of the deduction is "analysis." From this point of view it is supposed that when you engage in deduction you solemnly draw out of the bag the cat which you have already hidden in it. You declare, for instance, that all the *A*'s that are *B* are indeed *B*, and solemnly demonstrate that all the white mice must be both white and mice. It is unquestionable that many of the logicians of the past as well as the psychologists of recent times have conspired to give this impression of the deductive process. But whatever the psychology of deduction may be, any fair examination of the work of the exact deductive operations of science, and especially any examination of the work of mathematics, shows that deduction as it exists in real life is simply not this fiction of the older logical text-books. And yet to the psychological analysis of this fiction, with the natural result that such a process is not of very great importance, Professor Pillsbury, as I understand him, devotes himself in his discussion of the place of the syllogism in life.

But anybody who undertakes to deal with the psychology of reasoning ought, I think, to take account of the fact that there is nowadays a new logic, that this new logic is in considerable part the work of men whose attention has been attracted to the nature of the deductive process by a wide experience of mathematical procedure, and that this new logic shows us with regard to the syllogism, for instance, two things, first that the essence of the syllogism does not consist in the fact that a particular case is brought under a general principle; and secondly, that the syllogism is by no means the only form of deductive reasoning. From the point of view of the new logic, the student has upon his hands the problem that Poincaré has so well stated at the outset of his book, "Science and Hypothesis." This is the problem presented by the enormous *Fecundity of the Deductive Process*. Our own American logician, Charles Peirce, long since called attention to this fecundity. It is a fact of much philosophical importance. What I mean by the fecundity of deduction as a logical fact can be suggested by what Poincaré mentioned, and also by a summary of the matters to which Peirce has frequently called attention. Poincaré states the case thus: From the point of view of the older interpretation

of the nature of the syllogism it would seem impossible that a deductive science such as mathematics could do anything but draw out of premises what it had already more or less overtly or secretly put into them. Nothing novel could result. And in fact if the reasoning of mathematics were all of the kind that Professor Pillsbury supposes to be the typical deductive reasoning, mathematical science would consist in a process as stupid and monotonous as the process of taking the major premise, All men are mortal, and then looking up all the names in a directory and solemnly concluding to write opposite to each name the fact that since this person is a man he is mortal. But now as a fact mathematical science consists of nothing of the kind. The situation is actually this: you can write upon a few sheets of paper an accurate statement of a set of principles from which the whole science of the quantities of ordinary algebra can be deduced. That is to say, the principles of the ordinary mathematical analysis are capable of such a brief statement as this. But the consequences of these principles are such that novel results in vast numbers are annually discovered. These results are not stowed away in the premises in any such way as that in which the mortality of this man is stowed away in the assertion of the mortality of all men.

Poincaré, in the passage to which I have referred, suggests his own theory to account for the fecundity of mathematical analysis. His theory may as a logical theory be questioned. But the fecundity to which he attracts attention ought to be a commonplace to any one who has looked into any branch of mathematics with care. Peirce has called attention to this fact, and speaking as a logician has gone further. Following a lead of De Morgan's, Peirce has shown that any proposition whatever which has a definite meaning permits you to draw from it an infinite number of deductive inferences, all of which are possible without formulating any other basis for the deductions in question than the assertion of the original proposition and the synthetic power which one indeed has in his hands who is capable of understanding certain simple processes of the construction of relations. Let me mention the instance, famous in modern logic, which De Morgan first formulated; and which as it stands may appear trivial enough. If a horse is an animal, you can deduce from that hypothesis the conclusion that the owner of a horse is the owner of an animal, that the friend of the owner of a horse is the friend of the owner of an animal, and so on. Such deductions in an individual case such as that of the assertion about a horse may seem and are trivial enough. *But they have the character of novelty:* That is, the conclusion does not follow from the premises by the process of first stuffing a vast number of cases into a bag and then pulling them out one by one. But the process of deduction thus illustrated can be used and is used as an instrument of enormous power in those branches of mathematics in which one builds one system of relations upon another system. The number of ways whereby such deductive processes can be accomplished is presumably very great. And it is because such

processes are possible that mathematical reasoning possesses its great fecundity.

And now since such fecundity, such proof of novelties, is the essence of the live process of deduction as it exists in the deductive sciences, why should not psychologists study that live process instead of studying the dead body which some text-books have called the syllogism? And if they must study the syllogism as the supposed typical example of deductive reasoning, why should they confine their attention to considering the most traditional and trivial aspect of it?

As modern logic has shown, the really essential feature of the syllogism lies in the fact that what the logicians call the Illative Relation (that is, the relation which is in mind when you consider one proposition as true in case another is true) is a relation which has the property of so-called *transitivity*. That is, the essence of the syllogism may be stated by saying that from the pair of propositions "*A* implies *B*," and "*B* implies *C*" taken together you can deduce the conclusion "*A* implies *C*." In other words, it is of the nature of the illative relation that it permits the use of what James called the principle or axiom of skipped intermediaries. I can not pause to show why this account of the essence of the syllogism is logically correct. But the mere mention of this fact shows that those who analyze the process of deduction, supposing it to be represented by the traditional syllogism, and interpreting the traditional syllogism in the way in which Professor Pillsbury interprets it, simply miss the most interesting feature of syllogistic reasoning.

Nor is the aspect of the syllogistic reasoning which this emphasizes, the only one to which modern logic calls attention. Mrs. Ladd-Franklin long ago pointed out that the entire theory of the syllogism could be stated as a sort of comment upon the fact that a triad of propositions which she called "a triadic inconsistency" has, when considered as a triad, a certain set of logical properties. These logical properties, belonging to such a triad of propositions, can be observed by a process which is of the nature widely illustrated throughout the whole realm of mathematics; but this is certainly *not* the synthesis that Professor Pillsbury has in mind when he analyzes what he supposes to be a typical process of deductive reasoning.

Still more unfortunate for the study of the psychology of the reasoning process is that misunderstanding of the nature of deduction which supposes that the principal use of a deduction is to bring to pass a belief in a certain conclusion by virtue of an appeal to a belief in certain premises. This assumption, common in the recent literature of pragmatism, is false to the most essential use of deduction in the exact sciences. Mr. Russell has well emphasized the fact that, in mathematical science, just in so far as it is pure mathematics, you are not concerned with producing belief in the conclusions themselves. Your interest in pure mathematics, that is to say in that science which deals with deduction proper, lies simply in showing that *certain*

premises do imply certain conclusions. That is, you show that "*p* implies *q*," where *p* and *q* are propositions. The importance of mathematics for the empirical sciences is due to the fact that it gives you a means for testing the hypotheses by first finding out what are their logical consequences. Now it is essential for the fair and unprejudiced testing of an hypothesis, that you should *not* be too much disposed to believe in it before you test it. It is very important, when you do not believe an hypothesis, or when your mind is still perfectly open upon the subject, *to find out with exactness what would be true if the hypothesis were true*. Your purpose in deduction is therefore not to establish belief in certain consequences by virtue of a previous belief in the hypothesis upon which they depend. Your great interest is to produce *no belief whatever either in the hypothesis or in the conclusions from the hypothesis, until the logical issues are precisely defined* for empirical confirmation; and then you are *ready* to appeal to the confirming or refuting experience. It is a strange misunderstanding of the nature of the deductive process to suppose that its principal interest is an interest in producing belief in consequences. The sole logical interest of the deductive inquirer lies in his discovery that certain premises imply certain conclusions.

To sum up, then, this sketch: I assert that in the recent psychology of reasoning, *the nature of the deductive process and its principal purpose have been equally misunderstood*. Deduction in its more developed forms simply does *not* consist in an analysis of the premises. Nor is it intended to make you believe the conclusion. The true interest of deduction lies in the fact (1) that it is a process possessing an inexhaustible fecundity, and (2) that this fruitfulness results in giving you a knowledge that certain premises imply certain conclusions.

IV

But now let me briefly put before you some genuine deductive processes, and point out what problems with regard to their psychology can be aroused. Let me begin with the instance with which I have often wearied my friends, so that some of you who are here present will have heard me mention it. Raise the question whether a strip of paper can exist which shall have only one side. One would be disposed to settle the question empirically by observing that every strip of paper in one's ordinary experience obviously has two sides. If one passes from a consideration of strips of paper that have two ends, to the consideration of endless strips of paper, that is strips of paper made in ring shape, one sees that in an ordinary ring the two-sidedness of strips of paper still holds good. But if one takes an ordinary strip of paper, say two inches wide and eight or ten inches long, first twists one end of it 180 degrees, and then brings the two ends together, one has the resulting geometrical form of the one-sided ring. The first discovery that such a ring is possible was of

course an empirical discovery. But the geometers (I believe it was Möbius who first noticed one-sided surfaces) had their attention at once attracted to the mathematically interesting properties of this form. Now when such a form is viewed as a mathematical object, any one with mathematical interest naturally proceeds to an undertaking of the sort which is characteristic of mathematical science in general. One endeavors to deduce some of these properties from others, or to discover, as the ordinary mind would say, why these properties belong to any one-sided surface. Hereupon let me mention a problem that can be studied as soon as you have once taken note of the one-sided surface and have begun to make a study of the real sense or connection of its structure. Suppose a one-sided surface, a ring strip of the sort that I have described, to be cut down the middle, midway between what appear to be the two edges of the strip, and suppose the cut continued until it returns into itself, what will be the result? There are two ways of answering the question. One is the directly empirical one of making the cut. The other method is to endeavor to see before making the strip what must be the result in view of the one-sidedness of the strip. I once proposed the question to a class, and found a member of the class, who although not a student of mathematics, possessed a relatively clear visual imagination, was ingenious, became interested in the problem, solved it without cutting the strip, then tested his solution by an actual cut, and then brought me written out the process of reasoning whereby he had solved the problem.

The process of reasoning in question, or any process of reasoning by which the problem could be solved in advance of actually cutting the strip, is in part a genuine instance of deductive reasoning. Just because of the intimate mingling of empirical data and of exactly definable relationships, the case in question forms an admirable instance of the study of the genuine psychology of the deductive process; but I confess that no psychologist would make much of the study who was not fairly well acquainted with deductive processes of a certain complexity, – processes which in their more exact forms you will find anywhere in pure mathematics, where a symbolic language with an exact definition is used, as the only means of presenting data to the imagination.

Let me mention another instance of a deductive process of some complexity, but of great ingenuity and of interesting psychological relationships. We know that about 500 B.C. a member of the Pythagorean school discovered that granting the ordinary principles of metrical geometry as they were then and ever since have been used, the diagonal of a square could not be commensurate with the side of the square. The strictly deductive portion of this proof can be with fair ease distinguished from that portion of the proof in question which is indeed empirical and not deductive. That figures resembling squares exist is a matter of experience. That if you make a square exactly enough and large enough, and measure carefully enough

you will discover that by no rule you seem to be certain of stating the ratio of diagonal to side exactly in terms of whole numbers: this again is so far empirical. And the ordinary so-called axioms of metrical geometry, considered as principles about the constitution of the physical world, are of course generalizations from physical experience. On the other hand, the purely mathematical portion of geometry, that is, the purely deductive portion, consists in the discovery, not that the geometrical axioms are self-evident or otherwise certain, and not that the physical world has any properties whatever, but that certain assumed geometrical principles which can be stated wholly in symbols, actually imply certain geometrical conclusions. Now the early Greek geometer who discovered that the diagonal and the side of the square are from the point of view of geometrical theory incommensurable, was no doubt guided by the empirical difficulty of discovering any rule whereby a common measure for the diagonal and the side could be stated. Furthermore, he was not clear in his own mind as to the precise distinction between the deductive and the inductive part of his geometrical science. But he was possessed of the power to draw an exact deductive conclusion. And what he found out was that if certain principles of measurement and certain purely mathematical properties of whole numbers be admitted, the diagonal and side of the square are incommensurable. That is, he discovered that certain premises imply certain conclusions.

The process by which he discovered this we happen, though somewhat indirectly, to know. The instance is a remarkable one of the fecundity of the deductive process. The conclusion when the Greek reached it was a novelty. It seemed to him so novel and uncanny a conclusion that the Pythagorean school is said by a later tradition to have long regarded the whole matter as a mystery which must not be mentioned to the vulgar. It was reported that the man who revealed this mystery came to a bad end and received special penalties in the underworld, so closely in those days was exact science linked with *tabu* and with superstition. Yet no one who once goes through the little process of reasoning by which the ancient geometer established his result can remain without interest in the psychology of such a process.

V

You see throughout how my account of the whole matter is of course colored by my logical interests, and yet I freely admit that the psychological problems at issue ought to be considered without any undue reference to anybody's philosophical prejudices or concerns. I admit my own bias in the matter, merely because I am thereby enabled to call attention to what the live process of deduction is, and to point out that the recent psychology of reasoning has profoundly neglected to take account of some of the most elementary facts with regard to the nature of this process.

Charles Peirce long ago called attention to the general nature of the psychological processes which are in question in deduction. They are processes of the nature of ideal experiments. The instance of the one-sided strip of paper readily shows how many intermediate steps there may be between such ideal experiments and physical experiments with a strip of paper. On the other hand, as soon as you begin to reason, and to predict what will be true about a given strip of paper if certain hypotheses are met, with regard to its structure, you get an insight into the whole situation which you can not possibly get by cutting the strip of paper without adding the deductive process. And in general, wherever deduction is worth while, the testing of hypotheses after deductions have carefully been made whereby we predict determinate results of such hypotheses, has a wholly different value and interest from that which results from the testing of hypotheses without previous deduction.

The psychology of deduction may then well be characterized as the psychology of the *Gedanken-experiment*. The peculiarity of the experimental processes in question is that whether we use symbols, or diagrams, or mental images, our reasoning depends upon the fact that the objects in question are wholly under our control, so that in dealing with them we have no "course of experience," to use Charles Peirce's phrase, that is, no series of experiences which we have passively to await to see what they are, but are guided wholly by our own control, and are dealing wholly with objects which are what we make them. A given set of premises we construct in terms of symbols, diagrams, or figures, hereby expressing the meaning of these premises. Our deduction consists of the reading of this meaning from a new point of view. The fecundity of the process depends upon our power to combine at pleasure various constructions in various permitted orders and syntheses. The precise relation between such arbitrary objects, and the objects of ordinary experience, forms a topic of almost inexhaustible interest to the student both of logic and of the mental processes concerned.

I have thus indicated that the problems of the psychology of deduction have thus far hardly been attacked, mainly because psychologists have usually been so little interested in live deduction as it exists in mathematical science. So long as the myth still exists in text-books, that deduction is adequately to be represented by the form of the syllogism and the interpretation of that form which Professor Pillsbury cites and uses; so long as it is imagined that deduction merely lets out of the bag the cat that has already been put in it, our logic will languish and our psychology of reasoning will fail to fulfil the purposes of pragmatism or of any other doctrine of the reasoning process. So long as it is supposed that the main purpose of deduction is to produce belief in the conclusions, the psychology of certain of the most important human thinking processes must be lost. As a fact all tolerance, all considerateness in advance of action, all deliberate working out of ideal consequences of modes of behavior concerning which we deliberate, – all such processes would be

impossible. A great deal of toleration depends upon seeing how my opponent's conclusions are related to his premises, although I may have no belief either in his premises or in his conclusions. The process of deduction, in case of a practical deliberation concerning what it is best to do, helps us because we thereby learn in advance what *would* be the case *if* so and so were done, even if we ourselves have no tendency whatever as yet to decide in favor of the hypothetical course of procedure.

It seems to me then that the fecundity of the deductive process, the essence of the ideal experiment, and the genuine use of deduction, where it is not intended to produce belief but to give us insight into a connection of premises and conclusion, should form the topic of psychological studies such as thus far have attracted small attention.

VI

Some of the studies that I thus suggest may be of a nature to be treated by the methods of experimental psychology proper. I do not see why the psychological process of solving deductive problems that really illustrate the fecundity of deduction should not be, in certain cases, proper objects for detailed introspection. Let me mention a few possible cases. The one-sided strip of paper and a considerable number of related geometrical forms, may be made the topic of more or less direct experimental inquiry. Trained observers might undertake to solve such problems; namely, as deductive problems proper; that is, as problems of working out what conclusions follow from what premises. The deductive process proper could be separated in such cases from the special empirical materials used. And if the process is brief enough, or can be sufficiently well divided into stages to be the subject of introspection, there is much that is new to discover.

Let me mention another case of an extremely simple process of deduction of a type of which elementary mathematics is full, the process being one that involves a genuine ideal experiment and a genuine deduction. Almost anybody knows that if the sum of the digits of a number is divisible by nine, the number is divisible by nine, and conversely. Now let the psychological student be asked, if he does not already know the solution of the problem, *Why*, granting the ordinary principles of number, the numbers expressed in any decadic system must have this property. Let the ideal construction by which the problem is solved in a given case be a topic of introspection. The result could easily throw a light upon the psychology of reasoning which no discussion of the misused syllogism could possibly produce.

But the syllogism itself does indeed involve deductive processes that have a genuine fecundity. Mrs. Ladd-Franklin's theory of the syllogism, briefly restated by her in Baldwin's "Dictionary" and elsewhere, involves a deductive use of a construction which almost any psychologist can grasp with compar-

atively little trouble. The nature of the proof of the identity of the ordinary syllogism with Mrs. Ladd-Franklin's reconstruction, can be grasped by a process probably too complex to admit of any strictly experimental control. Yet if one once becomes familiar with this process and with repeated operations of it under controlled conditions, he would have material for the psychology of deduction.

There is another very fascinating problem in the psychology of deduction which has been almost wholly neglected. In my address before the Psychological Association years ago I called attention to the psychology of order as a problem still awaiting discussion. So far as I know, the problem has been little considered by psychologists since that time. But here is an aspect which presents curious phenomena. The relations "such as," "greater than," "to the right of," "to the left of," are transitive. That is, they follow James's axiom of skipped intermediaries. Now all those serial relations that can be expressed in these transitive dyadic relations can also be expressed in terms of the formally triadic relation "between." Thus, let *A*, *B*, *C*, *D* be four objects in a row. I can say, "*B* is to the right of *A*, *C* is to the right of *B*." I can conclude that *C* is to the right of *A*. And then I can define the relations of order in question. Now it is very easy to see that if *B* is to the right of *A* and *C* is to the right of *B*, *C* must be to the right of *A* so long as one interprets the relations of right and left as we ordinarily do. But suppose I give you the premises, "*B* is between *A* and *C*, *C* is between *A* and *D*," and ask you what follows. The conclusion is decidedly hard for most minds to work out. In other words, the triadic relations have a psychological difficulty which we do not feel in the case of the transitive dyadic relations, although we can express equivalent facts in both terms. The difference in question is hardly due to the fact that a set of three objects is more complicated to grasp than a set of two. For a little exercise in attempting to reason in terms of "between," as the geometers often do, will show that the psychological difficulty is out of all proportion to the numerical difference between two and three. The grounds for the difference in difficulty are presumably statable only in psycho-physical terms. But the matter is one for psychological research, and should be undertaken.

Over against these problems of the psychology of deduction which are possibly capable of a more or less direct experimental research, there are vast numbers of problems of deduction which can be attacked more indirectly, some of them by following the records of formation of new habits, some of them by means of more or less exact study of social processes. There exists, for instance, an indefinite range of possibilities for the study of the psychology of the arithmetical processes by a device which, so far as I know, has still been very little used, although I have repeatedly recommended it to students of educational psychology. We hear a good deal of effort to make out the details of the process whereby a child gets control of arithmetical computa-

tions. Now it is perfectly easy for any one to put himself near to the beginning of practical arithmetic and into a place where he has to learn very many of his habits as a computer over again, under conditions that will admit of a pretty careful experimental scrutiny of the way in which the new habits get formed, and which will enable us to make precise records of the growth of the new habits. The device in question consists simply in using, instead of our decadic notation and numeration, a dyadic, triadic, or other such system. Dyadic arithmetic is the simplest of all. In this one uses two digits instead of the digits from 0 to 9, inclusive. That is, one uses only 0 and unity; 1 standing alone will mean unity. If one uses two digits, the digit on the right will stand for units, the digit on the left for twos. The symbol 10 would now stand for two, the symbol 11 would stand for three, and so on. With the triadic system the places would be used exactly as in our decadic system. In the first place would be the units, in the next place to the left the threes, the third place to the left the nines, the fourth place the twenty-sevens, and so on. Now all numbers could be written in any of these systems. In starting with a new system, one could begin to perform additions, subtractions, multiplications and divisions, as with the decadic system. The possibility of an endless range of experiments, with mature persons, who, while retaining all their present arithmetical knowledge, would be instantly reduced to the position of young children, so far as some of the computations were concerned, all this makes an inquiry into the psychology of simple deductions of this type a very attractive one. Whoever wants to study psychology by becoming a little child has here a place for a wide range of study.

ON ABSOLUTE PRAGMATISM

Josiah Royce. "On Absolute Pragmatism." Selection from "The Principles of Logic" in *Logic*, vol. 1 of *Encyclopedia of the Philosophical Sciences*, ed. Arnold Ruge and Henry Jones (London: Macmillan, 1913), §21, pp. 120–123.

In our first section, the study of methodology showed us the relation of all scientific procedure to the Theory of Order. In our second section we have portrayed, in a largely empirical fashion, the Types of Order which characterize the exact sciences. Two of the concepts absolutely essential to the Theory of Order, we have already treated, indeed, so as to show *why they are necessary*. These are the concepts of Relation and of Class. For not only are these concepts actually used in the definition of every type of order, but as we have seen, *their necessity depends upon the fact that without them no rational activity of any kind is possible*. We have consequently insisted that these concepts unite in a very characteristic way – "creation" and "discovery," an element of contingency and an element of absoluteness. That a particular physical or psychical *relation*, such as that of father and child, should be present in the world, is as empirical a fact as the existence of colors or tones. That there should be physical objects to *classify*, this again is a matter of experience. And furthermore, every classification of real or of ideal objects is determined in any special instance, by a norm or principle of classification which we voluntarily choose. And in so far classifications are arbitrary, and may be said to be "creations" or "constructions." Yet, whatever else the world contains, if it only contains a reasonable being who knows and intends his own acts, then this being is aware of a certain relation, the relation between performing and not performing any act which he considers in advance of action. And thus relations amongst acts are in such wise necessary facts, that whoever acts at all, or whoever, even in ideal, contemplates *possible courses of action*, must regard at least some of these relations as present in the realm of his conceived *modes of action*. In a similar fashion, as we have seen, every sort of action determines a kind of classification of some world, physical or ideal. In so far, therefore, as the nature of relations and of classes in general determines the existence and the meaning of types of orderly activity, these types of orderly activity, and the order-systems which express their nature, are both empirical objects, "found" (since we experience their presence in our world); and are also *necessary* objects, because if we try to conceive that they are *not* there, our very conception involves modes of action, and hence restores these

necessary relations and classes to the world from which we had tried to banish them. We "construct" relational systems and classes in our ideal world. But we also "find" that at least *some* of these constructions are necessary.

A frequently asserted modern view, to which we have made some reference in the foregoing, namely the view called Pragmatism, asserts that all truth, including logical truth, has its basis in the fact that our hypotheses, or other assertions, prove to be *successful*, or show by their empirical workings that they meet the needs which they were intended to meet. From this point of view the logical hypothesis: "That there are classes, relations, and order-systems," would be true merely in so far as the acts of conceiving such objects, and of treating them as real, have, under the empirical conditions under which we do our thinking, a successful result. And thus logical truth, and the logical existence and validity of classes, of relations, and of the various types of order, would stand in the same position in which all the "working hypotheses" of an empirical science stand. These order-systems would exist, and their laws would be valid, precisely in so far as such ways of actively conceiving of the world have successful workings.

But, in the foregoing, we have already indicated that, so far as the existence of classes and of relations in general is in question, and in so far as the validity of certain logical laws is concerned, we are obliged to maintain a position which we may characterize by the term Absolute Pragmatism. This position differs from that of the pragmatists now most in vogue. There are *some* truths that are known to us *not* by virtue of the special successes which this or that hypothesis obtains in particular instances, but by virtue of the fact that *there are certain modes of activity, certain laws of the rational will, which we reinstate and verify, through the very act of attempting to presuppose that these modes of activity do not exist, or that these laws are not valid.* Thus, whoever says that there are no classes whatever in his world, inevitably classifies. Whoever asserts that for him there are no real relations, and that, in particular the logical relation between affirmation and denial does not exist, so that for him *yes* means the same no, – on the one hand himself asserts and denies, and so makes a difference between *yes* and *no*; and, on the other hand, asserts the existence of a relational *sameness* even in denying the difference between *yes* and *no*.

In brief, whatever actions are such, whatever types of action are such, whatever results of activity, whatever conceptual constructions are such, that the very act of getting rid of them, or of thinking them away, logically implies their presence, are known to us indeed both empirically and pragmatically (since we note their presence and learn of them through action), but they are also absolute. And any account which succeeds in telling what they are has absolute truth. Such truth is a "construction" or "creation," for activity determines its nature. It is "found," for we observe it when we act.

It consequently follows that whoever attempts to justify the existence of any of the more complicated systems of order that we have been describing in the

foregoing section, has a right to seek for some absolute criterion, whereby he may distinguish what systems of order are necessary facts in the world, – that is, in the world that the logician has a right to regard as necessary, – and what, if any, amongst these forms are either capricious, and unnecessary, or else are suggested by the particular facts of experience in such wise as to remain merely contingent.

The logician's world is the world of hypotheses, and of theories, and of the ideal constructions that are used in these theories and hypotheses. Now theories and hypotheses may be merely suggested to us by physical phenomena, so that, if we had different sensations from our present ones, or if our perceptions followed some other routine than the observed one, we should have no need for these hypotheses and resulting theories. In so far, the hypotheses are contingent, and the theories have only conditional value. Furthermore, some of our activities are indeed arbitrary, so that we may, as the common expression is, "do as we like." And when such modes of activity play their part in the choice or in the definition of our hypotheses, the logician cannot regard them as necessary. But, such logical facts as the difference between *yes* and *no*, are not dependent on the contingent aspect of our sensations, but on our rational consciousness of what we intend to do or not to do. Such facts have not the contingency of the empirical particulars of sense. And some modes of action, such as affirmation and denial, are absolute modes.

We can indeed suspend the process of affirmation and denial, but only by suppressing every rational consciousness about what we ourselves purpose to do. The particular deed may be arbitrary. But the absolute modes of activity just suggested are not arbitrary. We cannot choose to do without them, without seeking to choose, since choice is action, and involves, for instance, the aforesaid difference between affirming and denying that we mean to do thus and thus.

THE SOCIAL CHARACTER OF SCIENTIFIC INQUIRY

Josiah Royce, "The Social Character of Scientific Inquiry." Lecture Three of "The 1914 Berkeley Conferences" in *Josiah Royce's Late Writings: A Collection of Unpublished and Scattered Works*, ed. Frank M. Oppenheim (Bristol, UK: Thoemmes Press, 2001), vol. 2, pp. 20–39.

In giving at the outset an outline of the plan of this course, I emphasized the sharp distinction between the task of our first and second lectures and the task that lies before us in our third and fourth lectures. We have dealt with some illustrations of the theory of loyalty; now we are to consider certain problems of the theory of knowledge. As I warned you at the outset, these problems seemed to be in some respects remote from one another. What we have dealt with is the practical question of a significant plan for the conduct of life.

The doctrine of Loyalty asserts that you begin to find the meaning of life in so far as you discover the social group to which you belong, to which you are devoted, in the name of which you speak. The doctrine of Loyalty, as we have said, is in a sense the doctrine of salvation, for as I have insisted, the individual considered as a detached individual is essentially a lost being. He has not found himself, he cannot find himself until he discovers the group to which he belongs, until he is in love with the community. The doctrine of Loyalty, then, has been called by friends of man "the doctrine of salvation through team play," and such a doctrine it indeed is. Such a doctrine we have suggested. From its problems and interests we for the moment somewhat abruptly turn....

My next problem may be stated in this form. Human knowledge exists in many forms. Of these various forms two have proved to be especially important in the history of thought. The first form is the one that has been very largely represented in the history of philosophy. It has also found an expression in certain very highly technical branches of scientific inquiry, as for instance, in mathematics. The other of these two forms of investigation has found its most noted expression in the physical sciences. The contrast between the two types of knowledge which are here in question, and between the two kinds of investigation which we want to analyze, is somewhat familiarly expressed in the following form. Some of man's knowledge seems to be due mainly to the use of what is commonly called his reason. Some of his

knowledge appears to be due to what is also called commonly his experience, taken just as his experience comes. The theory of knowledge has to consider the two kinds of knowledge which are thus distinguished. And we may state the question that lies immediately before us by asking: How far is man's knowledge of the world due to reason? How far [is it] due to experience?

The question with regard to the relation between these two kinds of knowledge is fairly exemplified by the historical contrast between the sort of investigation which is more strictly philosophical or technically mathematical, on the one hand, and the sort of investigation which especially characterizes physical science on the other. We need to find out something about the methods which guide man in his more distinctly rational inquiries. We need also to become acquainted with the methods that guide man in his study of the facts of experiences....

[Moreover], in the history of human thought, the rational method of inquiry is exemplified by many systems of philosophy and is also exemplified by some portions of the inquiries of the mathematical sciences. This method has been brought in a very interested relation to a certain practically significant attitude of the inquirer. The rational inquirers, the constructive and creative philosophers, and again the mathematicians have been largely guided in their inquiries by the interests which again one may see in the history of thought as the interest of inquirers in forming opinions for themselves. Consequently, the interests which have been strong in the minds of rational inquirers have often been interests that were in their very nature what one may call individualistic interests. That is, the deductive methods have been very largely used by thinkers of an individualistic type. On the other hand, the students of the special empirical sciences have shown from an early period in the history of modern science a very strong tendency to a mode of inquiry which has involved, in a very interesting way, what I have already called team play....

We are just at the moment especially interested in the fact that this mode of inquiry into nature and into the meaning of life which the Greek philosophers began is not yet identical with the modern scientific method of inquiry. It is identical with a method which for long dominated the history of philosophy. That method of obtaining knowledge [which] I have already in general characterized as predominantly deductive, is a method which, whatever else it involves, depends upon thinking for yourself.... A great part of the history of Christian thought depends upon the effort which was always natural to the Christian consciousness to find what should be the proper relations between independent inquiry and tradition. And because of the direct or indirect influence of the Greek spirit, theological prejudice has never been able to stifle independent opinion in the minds of the Christian world.... We may sum up this sketch of a very complex subject by speaking of the deductive type of thinking as on the whole the individualistic type of thinking....

Thus, for instance, much as the early Greek thinker thought for himself, so at the outset of modern philosophy, Descartes throws aside all he has gained from tradition, declines to take notice of theological traditions, undertakes to doubt everything, and supposes himself to reach entirely original philosophical methods. Later in modern philosophy, while we have a constantly increasing sense that the individual philosophical thinker is making use of previous thought, and is dependent in a way upon previous philosophers, still there is the strong tendency which appears in new form whenever a contribution to philosophy takes its place in the world of thought – a tendency to make the right to think for oneself especially prominent....

Now in a very interesting and sharp contrast to the methods which have thus determined a great portion of the history of philosophy stand those methods which have become prominent in modern investigation. These methods have a very interesting character....

I may indicate the practical nature of the issue which is in question if I repeat that the methods of modern natural sciences are essentially the methods of team play. These methods are indeed very different methods of team play from those which were prominent in primitive thought. For the Greek spirit of individual and independent inquiry lies between primitive thinking and scientific thinking, and has profoundly influenced the spirit of the latter....

The methods of the natural sciences are largely those of induction, that is, they are methods that have to do with collecting the facts of experience and making generalizations upon the basis of these facts. But these methods have the curious combination of character to which I have just made reference. Let me enumerate these characters. First, the inquirer whose work lies mainly in the field of special empirical science is indeed interested in independent investigation. Secondly, ... the individual scientific investigator depends upon the work of his predecessors precisely in so far as that work is needed from the point of view which he deems important.... Thirdly, for this very reason the scientific inquirer has certain characteristics which are not prominent in early Greek philosophy, but which were prominent in the more primitive kind of thinking which savages and which the teachers of early civilizations had. As the savage was dependent upon the customs and the beliefs of his tribe, as the believer in any of the forms of religion which characterize the early civilizations was dependent upon the lore of his priests, or the traditions of his faith for the greater part of what he supposed to be his knowledge of the world, so in a very interesting fashion the scientific inquirer is dependent upon the work of other men. The scientific worker is suspicious of any extreme individualism in thinking, just as he is suspicious of too great use of deductive methods. He indeed demands of the scientific investigator a certain independent thinking. But at the same time he insists upon the fact that each such scientific investigator must depend upon the previous work accomplished in the science.

To sum up then, this suspicion of what one may call individual caprice in science, this tendency to limit somewhat strictly the range of one's independence of thought, this dependence upon the work of previous scientific investigators, all these features characterize the work of the special empirical science....

What I want to emphasize is that this distinction of methods is at once practical and theoretical. It corresponds to a distinction in the ethical life of mankind which has been of great importance.... The methods of the special natural sciences have indeed been methods dependent upon experience. But that is not their most important practical significance. The methods of the special sciences are allied to the methods of working together which constitute the most significant feature of the practical life of modern humanity.... There is, then, a very close connection between the ethical attitude of the scientific inquirer and the characteristic attitude of the loyal man. Both the loyalist and the scientific man combine an interest in the unity of the social order with a respect for individual freedom of inquiry....

The question whether philosophical methods can always become scientific is one of the burning questions of philosophical discussion at the present day. There is no doubt of the propriety of the effort to ally the methods of philosophy, the methods of inquiry which have been prominent in the past, with the methods of team play which characterize the scientific inquirers and the actual inductive investigations which they carry on. I am perfectly ready to say that the philosopher of the future will become increasingly scientific in his methods.

What I am interested now in emphasizing is that in so far as this takes place, philosophical thought without ceasing to be independent thinking and to use individual inventions and the freedom of individuals, will become increasingly loyal in method, will be more and more an effort to express, as the natural scientific method expresses, the purposes, the insights, the discoveries of the community.

Of course, that the real facts of nature are facts which exist for many people, we can all of us notice in dealing with the most ordinary matters of natural knowledge; and common sense, like the primitive man, is always social. Man, the gregarious animal, has always regarded nature as in some ways common property of the experience or knowledge of the group or the tribe. Men have always been more or less aware that the natural facts are those which we in common observe and can use. As a gregarious animal, man is fond, of course, of this common, of this social experience of natural facts. But it is characteristic of the development of modern science that what thus lies deeply grounded in the gregarious nature of man has become conscious so that just as man the gregarious animal becomes loyal when he has first become investigative enough to become aware of how much he loves his chosen social group, so man, the gregarious observer of nature, man the

animal that always tended to hunt in packs and to fight in groups and thus to take over the common experience as the property of each individual man, becomes on the scientific level clearly and consciously aware that he distrusts private individual observation unless this receives the systematic confirmation of the group.

Thus then the scientific methods like the practical methods of the loyalist depend upon a clearly conscious interest in the common social interest. We have later to see how the scientific method of knowing nature is bound up with the ideal and positively significant aspect of the loyal practical consciousness which I tried to illustrate in our opening lectures....

To sum up our results: whatever the methods which are characteristic of the natural sciences, they depend upon and express a very clear and conscious recognition on the part of the scientific inquirer in the range of inductive science that the truth which he seeks when he deals with nature is truth that belongs to the community. And thus the methods of inductive science and the practical attitude of the loyalist have an intimate and close connection which we need to understand somewhat better than we usually do....

Hence, there is at present no more powerful teacher of Loyalty than the scientific spirit. And for that very reason there is no more significant mode of bringing about the world peace, concerning which we hear so much, than spreading not merely the scientific spirit but its application to human life....

I now wish to call attention to the connection between induction and the scientific spirit which was first emphasized by the man whom I named in my opening lecture, Mr. Charles Peirce. The contribution of Charles Peirce to the logic of the inductive method is a very technical contribution.... Our scientific methods depend upon certain methods which are not only methods of observation but also methods of reasoning. The methods of reasoning, in so far as I call [them] technical inductive methods, stand in a fairly sharp contrast from the methods used, or at least predominantly used, in the mathematical sciences.

Deductive methods are those familiarly known to you in computation of all kinds. Granted the items that are entered in an account book, the making up of the balance sheet of a commercial institution at a given moment may be, after enough of these items have been collected, a matter of computation. A computation is deduction....

But the special natural sciences make use not only of experience but of a set of methods which are predominantly inductive. Of course in a general sense they are rational methods, for they require a very high degree of intelligence. But they are methods which are essentially bound up with the interest in collecting and of course in systematizing our human experience. Now, one who makes use of the inductive method of course infers. That is, he draws certain conclusions from certain premises.

His premises are assertions about what he in his reasoning already supposes to be true. Just as one who computes the tables of the nautical almanac, in

so far as they deal with lunar distances and eclipses and such facts, presupposes as true certain premises relating to the laws of motion of the heavenly bodies, *just so* an inductive inquirer presupposes certain premises which are in general known through the experience of observers, or, as we have said, through the experience of the scientific community. He engages in inductive inferences when he draws a conclusion to the effect that if these presupposed premises are true, then this and this inductive inference can probably be made. The simplest example of such an inductive inference which happens to have found a prominent place in the elementary textbooks of logic is the inference which we make regarding such laws of nature as are popularly expressed by saying, "We human beings must all of us die; we are mortal." Another simple instance of the inductive inference, also rather frequently used in logic textbooks, is the inference that the sun will rise tomorrow....

An inductive inference differs from a deductive inference in the way which Charles Peirce always from the outset of his work emphasized as a much more essential difference than the older logic textbooks were supposed to recognize. An inductive inference, as you can see from the case about the sun rising tomorrow, or the inference about the dying of men in the future, is an inference which has no necessity about it.

On the contrary, it is what one may call a probable inference. If the sun has long risen, then it is probable that the sun will continue to rise. If men have constantly died up to the present time, it is probable that the mortality of men will continue. Since all our knowledge of the special facts of nature can be expressed up to the present time in the form of certain statements of premises which express the results of observation, all our inductive inferences have the character just pointed out. That is, speaking with the strictest carefulness about how far an inductive inference has validity, we may say an inductive inference is probable. If the premises are true, then the conclusion is not indeed certain or necessary, but probably follows. Therefore, for the purposes both of logic and of the general theory of knowledge, inductive inference is [an] essentially probable inference. It lacks the necessity of inference.

And the problem about the so-called technical theory of induction is this problem: What is meant by saying a certain inference is probable? The importance of this technical question, at least for logical theory and also for the general theory of knowledge, appears when we reflect that all our present knowledge about nature, in so far as we can express it in inference, takes the form of this kind of probable inference. The sciences, in so far as they are natural sciences, do not [possess][1] a deductive and necessary character, like pure mathematics, or like the sort of knowledge which you have whenever

[1] Emendation of "consist in" in the typescript version.

you compute the sum of a column of figures. Our knowledge of nature, all of it, has the inductive character. We cannot say that, if our observations are correct, such and such laws of nature must in future follow such and such processes. We can only say that it is probable that these and these are the laws of nature. It is probable that in [the] future nature will follow this and this course, just as it is probable that the mortality of man and the sunrise will continue for a great while....

So then, to face at once the central technical question, what do I mean when I say that, if certain premises are true, a certain conclusion is probable? What is this probability? What is this curious predicate "probable," which is not identical with the predicate "true" and not identical with the predicate "false." For what does this predicate stand? It is a predicate especially forced upon us by the limitations of our experience. We should all like to know what must be true. In dealing with nature and with life, we all have to put up with what is probable. It is a perfectly fair question: Wherein consists the nature of probability? In what sense is something probable? ...

Hereupon let me state the answer which Charles Peirce in his logical researches early proposed to this question. For the moment I state that answer dogmatically. I shall try to show you its practical bearings and to illustrate them briefly. Charles Peirce's answer was simply this. When I tell you that a certain proposition or inference is probable, I mean something which refers not probably to anybody's state of mind, but most decidedly to the world of fact. I mean something that can be expressed in statistical form. When I say such and such a proposition is probable, I mean, if I do not specify more definitely the probability to which I refer, I mean in general as a matter of fact a proposition of that kind [which] is more frequently true than false.

An illustration will show you how such a proposition can be made not only for things such as refer to probability in general but such as refer to some very definite probability. When an insurance company decides upon the rate you have to pay for a policy on your life, the insurance company speaks of your expectation of life, or of some other interesting character of fact or assertion about your life and its chances in perfectly definite and statistical terms. When you say, "I shall probably be alive tomorrow, or a year from now, or ten years from now," you may be expressing merely your state of confidence or doubt. This state may vary with your moods, with anything that happens to make you confident or doubtful about your life. And the word "probability" thus used has no scientific significance whatever. Probabilities that assert merely states of confidence or of doubt have interest as features of your private experience. They have no interest for the insurance company.

When the insurance company speaks about your probability of life, or about your expectations of life, its assertions are reports of fact, not about you individually, but about a group of persons to which you belong. In speaking of the probability of your living ten years, the insurance company makes use

of some report of facts which enables them to say, "Persons of the class to which you belong – and in particular of the age and health and constitutional history which you are able to show – persons of this class or group are such that such and such a percentage of them live ten years, or will be alive at the end of ten years from a given date. If, for instance, this man is thirty years old, there is a certain probability that he will live until sixty. That is to say, a certain percentage of a large group of men who are in good health and thirty will be alive at sixty. In terms of such assertions about facts, the insurance company makes all those assertions about the probability of life which lie at the basis of its estimates of the value of a premium which a man ought to pay."

So then, when I say without specifying, "This proposition is probable," I mean this proposition belongs to the class of which most member [propositions] are actually true. When I specify the probability and say what the betting man asserts when he bets on odds, and what the insurance company says more exactly when it issues a policy, "The probability of this proposition is such and such a percentage of a unit of probability, or of what may be called simple truth," then I mean this, so long as I am speaking not of a state or mind, but of facts. I mean this proposition belongs to a class of propositions of which in fact an observation shows a certain proportion are true. I do not know this proposition is true, but I may know that it belongs to a class of which 50%, 10%, 1%, or 99%, and in extreme cases, 100%, are true. The extreme case, of course, would be identical with one saying, "This proposition is true." The case where one says it has such probability is the case where one can assert the statistical proposition which I have just exemplified.... Thus all assertions about probability, and in particular all assertions about inductive inference, are assertions that possess a probability which is always definable in terms of facts, that is, in terms of statistics. Having used these illustrations, I must ask your patience for one more thesis which is characteristic of Peirce's theory of induction, and which makes me call the theory the insurance theory of induction.

The practical significance of these considerations may more clearly appear if one lays stress upon a matter which Charles Peirce was, I think, the first to point out. If this view concerning the meaning of the term "probability" is the right view; if, when I speak of the probability of a judgment, I do not refer to the degree of confidence which I have in that judgment; if, when I speak of the probability of an inference, I am equally not laying stress upon the degree of confidence that I feel in that kind of inference; if, on the contrary, in both of these cases I mean by the probability of an assertion or of an inference this; namely, that in the long run a certain proportion of the assertions or inferences of some definable class are true, then the effort to make my assertions probable and the effort to make my inferences probable becomes an important effort only when, not my private interests, but those of a community are concerned.

In fact, it is the interest of the man who follows scientific methods, not that he should increase the degree of confidence that he personally has in his methods, in his assertions, or in his inferences; it is his interest that he should so assert and so infer that as large a number as possible of inferences of the type in question are true. And in consequence it is his interest that the community of scientific men should be guided by methods which, never infallible and frequently erroneous, are, nevertheless, in the long run actually true in as large a proportion of cases as possible. The interests of the inductive reasoner, the interests of one who uses scientific method, are interests in the success, not of the individual scientific reasoner or investigator, but in the scientific community. Scientific method is never infallible.

On the contrary, all the results of scientific method are subject to error. And the scientific community, the group of those who are engaged in carrying on scientific research, gains on the whole by following the scientific methods and by using the other methods of inductive inference. Because by such methods and by such modes of inference the proportion of correct judgments, and the proportion of correct inferences increases and actually tends toward a maximum.

As Peirce was the first clearly to point out, if man had no social interests, if, for instance, he were thinking only of the salvation of his own soul, and if for him the salvation of his own soul were something of such interest that the whole world itself would be to him not so valuable as the salvation of his own soul, then when that man made a probable inference, he would be taking a risk too vast for him to estimate in terms of any reasonable use of the term probable. Such a man would be like one who was asked whether he was willing to take a risk that was greater than all the gains that he could possibly hope to make at any future time in case just that risk happened to go against him. Such a man might, indeed, take such a risk, but there would be no reason why he should do so. He might say, "I believe that if a thousand men take this risk, only one of them would fail." But if he had to add, "If I take this risk and fail, I should lose absolutely everything in this world and in the next," then you could give this man no reason why his decision should be determined by saying, "It is probable, or the odds are a thousand to one that this judgment of mine should be right." If this man would have to think, "If this risk went against me and if I lost my own soul, or lost everything else in the universe that is valuable to me, and if indeed my interests alone are to be considered in thinking of this decision of mine, well, then, if I am willing to take so small a risk of losing everything, my soul included, that willingness is due simply to my own boldness, or to my own indifference to the fate that may happen to me. There is no reason why I should take this risk even if it is represented by a small fraction of what is called probability, or on the other hand, by a fraction that is very near to unity, and that so suggests that I am myself concerned that the risk will turn out in my favor. "For whatever you call the probability," so this man might say, "what

is at stake for me constitutes everything that I value. So if I am simply prudent, I will take no risks. On the other hand, if I choose to take this risk, I can give no reason by simply using the word 'probability,' or by merely mentioning the fact that only a small proportion of such risks if taken would turn out failures. All that kind of reasoning would leave me free to decide whether I personally choose to take that small risk or not."

Entirely different, however, would be the situation which is actually the situation of anyone who is reasoning about questions of natural science, or about those problems of common sense in dealing with which we use scientific methods. Such a person would say, "When I declare that a certain proportion of the assertions or inferences of a given type turn out to be correct, my assertion bears not merely upon my possible choices, or decisions, or successes or failures, as a detached individual. When I speak of the probability of scientific assertion, or of inductive inference, I am speaking in the name of the large community of scientific investigators. I am interpreting the will of that community. That community desires that in the long run as large a proportion as possible of scientific assertions and inferences should turn out to be correct ones. It is possible to declare that that proportion can be increased by using certain inductive methods, or as they are called, scientific methods. These methods have been themselves found by the experience of the community. They can be analyzed with considerable accuracy by the inductive logician, that is, by the student of scientific method."

It is the will of the scientific community, then, that these definable methods, which tend to increase the proportion of scientifically correct judgments and inferences, should be followed, and that other methods should be avoided. When the community, the scientific community gets its will expressed, nobody can guarantee to the individual scientific worker who makes this inference on this occasion that his inference will be correct. And nobody wants to guarantee to him this assurance. Nobody can probably tell the individual scientific worker how confident he ought to feel. How confident a man actually feels is a matter that concerns, indeed, his own private personality. It may satisfy his soul to feel confident that his inferences are correct but this feeling of his has no bearing upon the scientific importance of his inductive methods. What is important is to know whether, in case the scientific community follows that kind of method, it tends in the long run to success, and what it also interests us to know, approximately or roughly, the proportion of successes resulting during the life of the scientific community from following good methods of inductive inference, good methods of scientific observation, good method of stating and using assertions, hypotheses, and other means of expressing scientific opinions.

The inductive logician hereupon says to the individual inquirer [about][2] things, "Observe thus, infer thus, and your inferences or assertions will be of

[2] Emendation for "that" in the typescript version.

the type such that if the methods which you use are universally employed in the scientific community, a large and increasing number of scientific assertions or inferences will be actually true." From this point of view, it is of the very essence of scientific method that it concerns the interests, not of the detached individual, but of the community. It is the essence of inductive inference, where it has an exact and scientific character, that whether or not it happens to increase the confidence which somebody feels, and whether or not it leads to truth or to error, it does on the whole if followed lead the scientific community to an increasing proportion of cases of correct predictions, of accurate inferences, of verifications of hypotheses, and so on.

Throughout his writings Peirce is fond of expressing this view of the nature of scientific method by saying that scientific inferences, in so far as they follow precise method, are inferences that have an insurable value. The investigations of science are of very widely important practical applications. But it is not necessary for the logician to confine himself, or even devote himself very largely, to considering the practical applications of science in order that he may know what constitutes good scientific methods. The logician may entirely ignore the fact that applied science is practically very useful. When be speaks of the insurable value of an assertion or of an inference, he means according to less substantial things.

Suppose every error of the scientific investigator were scored by some omniscient insight as a disaster, as something of the nature of an explosion, a fire, a death, or whatever calamity you please. Suppose when one speaks of the probability that a certain scientific assertion or inference is true or erroneous, one were speaking in the name of the community of scientific observers. Then one would deal with the value of a scientific method and with the policy which ought to be pursued by a scientific observer, investigator, or inquirer, very much as one speaks of how the conduct of the individual should be guided in cases [wherein the][3] individual has to take risks, while the risks could be insured.

As you well know, if an individual man considers the future of his own house, or of his own life, he may feel all sorts of degrees of confidence as to whether his house will or will not be burned, as to whether he individually is to survive a year or is not to survive. These feelings are personal. You can give a man no rules as to how they [these feelings] should enter or should influence his life, unless, indeed, you lay stress upon the. kind of man he is and the kind of value his personal affairs have in his life. But if you were addressing the men of the community, and if they are already able to form themselves into associations, or to bring themselves under the care of corporations that take interest in fire insurance or in life insurance, or any other kind of insurance, then you can say that it is reasonable for the people of such a

[3] Emendation for "that" in the typescript version.

community to guide their conduct according to what is called the insurable value of a risk.

Suppose as a fact we could say that a certain proportion of houses of a certain type, in a certain portion of the country, or in the country at large, or in cities of a given size, do burn within a year from a given time. Then we can say to the individual: No matter what you hope or fear, the community loses yearly such a proportion of the houses of this type. If the community meets this loss in any steady way, it provides a fund, represented perhaps by the accumulated funds of the insurance corporation. From this fund or from similar funds such losses are met. If your house, or your life, or any other possession of yours, constitutes an insurable risk, that means first, that whatever your hopes or fears may be, the damage done, to the beneficiary in favor of whom you might insure, the damage done if your individual risk turns out well, can be met, in case the corporation or the association which is ready to insure you, receive a certain premium, and hereupon contracts that, in case your risk turns out well, your beneficiary shall receive a certain compensation.

If the risk in question is of a sort concerning which no useful statistics can be, or have been, collected, or if your risk is such that it cannot in any reasonable way be classified at all, then your risk is uninsurable. But if your risk can be put into a class, and if the insurer can be found who will insure that risk for the sake of a certain beneficiary, then, while nobody can tell you anything about what will happen to you or to your individual risk, or to any other detached individual, one can say, as the insurance company says, "Your risk can be fully covered for such and such a premium."

Now, as in the practical world there are communities that together suffer from all the failures that come to individuals with regard to unexpected death, or fire, and as in the practical world, just because [there][4] are such communities, just because "no one liveth to himself and no one dieth to himself," just because nobody's fire loss is merely his own, but does affect his possible beneficiary, his creditors, his heirs, his assigns, or others, therefore the devices of insurance enable losses to be in a sense made good to beneficiaries, *just so* in the work of scientific investigation, if for the time being you regard all errors as disasters or as failures, and as in that sense similar to fires and deaths, you can view the whole situation in this way.

The scientific community is interested in successes. A logician who defines in an abstract way the plans of the scientific community, that is, who advises what scientific inference ought to be made, would be glad if he could say to the individual, "Reason thus and thus, and your conclusion will be true if your premises are true." If the logician could say this [of at least][5] the portion of the

[4] Emendation for "they" in the typescript version.

[5] Emendation for "or in" in the typescript version.

scientific work of which he could say this, [then] his reasoning becomes deductive and necessary, and his conclusions must be so, granting their premises.

But in the field of inductive inference the logician can give no such precise rules. He cannot say, "Infer this and this from such and such premises, and your conclusions are sure to be true if your premises are true." He can say to the individual investigator, "I cannot tell you whether your inferences are correct or not. For you are engaged in inductive inferences whose premises do not secure the truth of their conclusion, whose reasonings have only a probable value." What the logician means by this probable value is that which has now been explained, "I can tell you [that] if you infer thus or thus, the method of your inference is such, that if the scientific community consists of people who follow such methods, a more or less exactly definable proportion of the inferences made by such a scientific community will turn out to be right inferences."

The inductive logician can therefore continue, "My comment upon scientific method no more assures the individual investigator of the correctness of his inferences than the insurance agent, or actuary, or other representative of an insurance community, can tell the individual when his death will occur, or whether or not his house will be burnt." What I, the logician, can say, speaking in the name of the scientific community, is something of this sort. "If you, the individual investigator, regard the work that you do as an investigator, as an observer, as a reasoner, as your contribution, as, if you please, the premium that you pay for the result that you want to secure through making this contribution to the work of science; [again] if you regard as your beneficiary so much of the scientific community as happens to continue to follow your methods, in your branch of science – that is, if your beneficiary is the group of scientific investigators to which you belong; [and again] if you regard the whole community which insures you as the whole body of scientific investigators in this and in all future time, *then, indeed*, I the logician can say to you this:

By the premium that you pay in following good methods as well as you can, you in the first place insure that, in so far as your methods are followed by your science, the little community of workers (who work in your science and according to your methods) shares in whatever benefits accrue in the long run to the whole body of scientific investigators. Inductive science will often fail precisely as commercial enterprises often fail. Thinkers and sciences will go wrong, as they have often gone wrong in the past. For instance, the medical science of today will be so altered by future knowledge that the most of our present textbooks, and some of them very quickly, will become useless. There is no road that leads with assurance to any one desirable set of scientifically true assertions and inferences. There is no scientific security against those disasters called errors, which we have compared for the purposes of this argument to fires, to deaths, and to other calamities.

But this can be said to the individual worker in some difficult and rapidly changing science, such, for instance, as a medical science: There are certain inductive methods which can be shown to tend towards producing a large proportion of correct rather than erroneous inferences that one can say the great scientific community – the community of all the investigators who follow good methods of scientific research – does tend in the long run to make an increasing proportion of correct scientific inferences. Hereby various benefits, some of them in the actual sense practical, some of them with far-reaching theoretical significance, tend to come to humanity. In these benefits your science will share, if you help your fellow-workers to follow good inductive methods, or if in your own way you tend to create the minor community of your special science, which by making the good type of inference conforms to precisely that sort of thinking which leads the total scientific community towards a continual progressive power to discover the truths of nature.

To the individual worker, then, the inductive logician gives the command, "Work thus and thus. That is, apply to your problems these inductive methods." The individual scientific worker is in general doing what he can to form and advance his own science. In doing his work he offers aid to his science, which may be regarded for our present purposes as beneficiary. The relations of the whole community of scientific workers to the natural world of our human experience are such that this scientific community taken as a whole is sure to progress, and is sure now that scientific method has been discovered, to follow the methods which an inductive logician endeavors to define. Once more, then, to the individual worker the logician can say, "if your methods are sound, your scientific results have an insurable value."

One may express this insurable value in these terms:

For your community you the individual worker have paid the premium by your work in accordance with scientific method. Hereupon, so far as in you lies, you have insured the result that the general tendency of science to progress will through such aids as this accrue to the advantage of your science. That is, to continue the same metaphor, By your payment of your service, you insure your beneficiary a certain right to share, in the long run, in the indefinitely extended future progress of science.

The individual worker may fail; his beneficiary – that is his own science – may in time pass away from the field of scientific interest as Alchemy did, as Astrology did, as several forms of psychical research have already done, and as very possibly some other forms of psychical research may yet do. But so far as such matters are matters of scientific investigation at all, what interests the individual scientific worker is the fact that he can do work, that is, to continue my metaphor, he can pay a premium, which insures for his science – that is, for the company of those who work with him in the same scientific field – the general advantage of the scientific community. And the sound

inductive methods are those which, however often they fail in the special case, will always tend toward the progress of the scientific community as a whole, precisely in so far as such methods are persistently followed.

This is what I mean by the insurance theory of induction. It depends upon taking note of a real analogy between inductive inference and the methods of the various special sciences and the practical procedures upon which insurance companies are based. Extremely significant for the student of the practical philosophy of loyalty is what Peirce points out in his first essay upon the subject; namely, that inductive logic can have no interest for a man who was concerned only in the question as to whether his own personal and private inductive inferences were true or not.

As nobody would insure [that is, would obtain insurance] who had not in some sense defined a beneficiary, to whom his insurance would be paid if it became due – even if this beneficiary were, as in fact he often is, the future self of the person insured; [again] as nobody would insure who is not prudent enough to think of his own future self and not socially minded enough to be interested in some beneficiary – for instance, in his family, or in his creditors, or in his heirs; and [again] as nobody could insure unless there were a community to which he belonged, and in which the results of the manifold risks, successes, and failures lead to some accumulation of the results of success and failure; [and] in brief, as insurance is impossible except for members of communities who take interest in some aspect of the welfare of their communities, and whose communities take in some respects an interest in the welfare of their individuals, *so* nobody could have any logical interest in scientific method, unless he were a member of a scientific community and unless his affairs were bound up with the affairs of other inquirers.

It is with good reason, then, that the inductive sciences have grown up with the appearance of new types of social order. Independent and individual thinking plays its part in science, precisely as it is essential both to scientific discovery, and to philosophical creation and investigation, but when scientific method takes the form of inductive inference, it takes a form which is one determined by the relation of the individual investigator to the labors of the scientific community.

Of course, in order to make all this doctrine precise, and in order to explain in detail its meaning, I should have to show what Peirce tries to show at length; [namely,] (1) how we find out that a certain type of scientific inferences is such that if they are steadily pursued, and more or less definable, a large proportion of these inferences will be correct; and (2) how we also can show that this proportion of correct inferences tends for the whole scientific community steadily to increase. But that, as Kipling would say, is another story. That is the theoretical, the most important part of an inductive logic.

I can here speak only of this one fragment of the theory of inductive inference. The picture which Peirce gives you of the work of an inductive

science is on the whole as follows: A method of using experience has been found which any individual investigator can within his own limits apply and which becomes especially significant because a great many people can apply it together. This method is applied in the course of the history of science, and, as we may reasonably suppose, will be applied in an indefinitely long future, by what we may call the scientific community, that is, the whole body of workers who make use of such methods in dealing with nature. The nature of the methods in question is such that for this community in the long run there are, indeed must be, an advance on the whole in proportion to the correct inferences made. That is to say, there must be such an increasing proportion of correct inferences if the natural world which we study has, as Peirce would say, any definite characters whatever, any definable constitution, any order in it.

Peirce has shown that we need not presuppose the natural world to be what is often called uniform, or to be what many philosophers have defined as reasonable, in order to be sure, and sure in ways that of course involve some deductive inferences, that the scientific methods applied by the scientific community will in the long run lead to an increasing proportion of correct inferences. But it belongs to the special discussion of the theories of inductive logic to point out why this must be the case and why the scientific community as a whole must tend to a genuine scientific progress so long as investigation keeps on uninterrupted....

When a new science begins, it may run out in failure, or at least in relative failure. Nobody can guarantee to a new science success.

Within the field of each science there are individual workers. Nobody can guarantee to any one of those workers that any one of his scientific or inductive inferences is, individually considered, sound. Inductive logic points out to the individual worker how he can pursue methods which in the long run lead the scientific community to success, in so far as this whole community in its more united activities follows these methods. Such methods if followed by the individual investigator accrue to the advantage of his beneficiary, that is to say, of his individually pursued special science. In so far as a given scientific investigator actually works alone, tries his own experiments, tries out his own hypotheses, makes his own inferences, he may act as does a man whose only beneficiary is himself, or who as common sense states the situation, insures himself. In some respects every men insures himself who, as one says, takes his own risks. But while such a lonely worker, like each one of us [assuming] the particular risks of his own private life, can give no valuable interpretation to the probability which he attaches to his own private opinions, unless he at least in ideal regards himself as a member of the community, it still may be said that it is reasonable even for such a lonely worker to pursue the scientific methods which in the long run lead to the progress of the whole scientific community. Such a lonely worker thus can

be sure that he follows a method which in the long run accrues to the value of himself as a scientific worker, who will take interest in the fact that, if he does not succeed, he has done his best to deserve scientific success.

[POSTLUDE]

Some of you who hear this account may ask how this doctrine of Charles Peirce's differs from what William James taught as Pragmatism. I have no time to dwell upon this distinction at any length. I can say at once that in so far as I understand James, his theory of truth was in its essence very highly individualistic. That is, when James taught that propositions are true in so far as they work, he was thinking of workings which come to light in the experience of human individuals. He insisted, indeed, that we all of us count each the experience of other men as of importance in establishing the truth of assertions. That is, from James's point of view, the scientific worker is what one might call simply altruistic. That is, he says my propositions are true for me in so far as experience shows that they work. Your assertions are similarly true for you so far as they work for you. And speaking in general, we can say truth belongs to assertions so far as they work for somebody, are verified in the experience of any individual that you please who is actually [alive][6] and who finds these assertions true.

What James never made explicitly clear about this theory, and what, as I believe, he never saw, was that the workings which are in question, when the community is concerned, have existence in so far only as the community is a reality. James, so far as I understand his philosophy, never formed any definite idea of the community, either ethical, or social, or spiritual. He loved individualism, and appreciated mysticism. Loyalism he, indeed, practically illustrated in much of his most beneficent and generous life. But in doctrine he was never a loyalist. For in James's world, there were no communities which seriously interested him. For whenever James thought of a community, he thought of something having a conventional estimate of truth. And such estimates were repugnant to him.

Charles Peirce, on the other hand, although in his peculiar life he was very much more nomadic than James ever could have been, and although his strange nature condemned him largely to solitude, to spiritual isolation, and to a persistent inability to cooperate with others, was in ideal, and very sincerely, and in his fragmentary writings, very effectively a loyalist. The world of the spirit had from the point of view of his philosophy a very genuine unity about it. As a logician he used to like to express this by saying that he was no nominalist and that the great defect of modern philosophical thought, as well as of modern social life, has been its persistent nominalism, that is, its interest in detached individuals, in their detached success, in their individual failures, and in their mutual impenetrable isolation. What consti-

[6] The word "alive" substituted for a blank in the typescript version.

tuted the tragedy of Peirce's life gave him the warnings upon which his philosophy and his logic are based.

While then he invented the term Pragmatism, his own doctrine was never that of James. It is a scientific community that wins in the advance of science. And despite all vicissitudes of research, this winning of the scientific community is progressive. And on the other hand, the individual worker who draws his own inferences is in the world of scientific investigation what we all are in the fields of our particular lives, a creature of risks, subject to disaster, and unable to define his problems in terms merely of his own feelings of certainty, or in terms merely of his own hopes and fears. What scientific method guarantees to the worker is closely analogous to what loyalty guarantees to the individual doer of everyday deeds – namely, union with the spirit of his community and assurance that, however and wherever he fails, he can follow methods by which the community succeeds, and can therefore insure the advantage of his beneficiary, in case he seriously undertakes to work in the spirit of this community, and in case his beneficiary is also a portion of this community.

Section Two

Evaluations of Royce on Pragmatism

ROYCE'S WORLD AND THE INDIVIDUAL

Charles S. Peirce. "Review of Royce, *The World and the Individual, Second Series*." *The Nation* 75 (31 July 1902): 94–96.

Professor Royce's second and concluding volume discusses questions of intimate interest to everybody. It is more persuasive than the first, of which it enhances the significance. The design of the whole now comes out – to introduce into the Hegelian philosophy of religion such rectifications as must result from recognition of scientific conceptions worked out during the century now completing itself since that philosophy first appeared. Of these new conceptions, some are psychological, some logical; but the chief of them are the new mathematical ideas which cluster about that of an infinite multitude. Mathematicians, perhaps, still linger on the stage, who, in their best days, used to be quite positive that one cannot reason mathematically about infinity, and used to feel, like the old lady about her total depravity, that, this cherished inability being taken away, the bottom would fall out of the calculus. Such notions are obsolete. Various degrees of infinity are to-day conceived with perfect definiteness; and the utter misapprehension of the metaphysicians about it, above all of Hegel, glares. As a first serious attempt to apply to philosophical subjects the exactitude of thought that reigns in the mathematical sciences, and this, not on the part of some obscure recluse whose results do not become known to the public, but on that of an eminent professor in a great university, to whom the world is disposed to listen with attention, Royce's 'The World and the Individual' will stand a prominent milestone upon the highway of philosophy.

Our space will permit only the most salient features of Professor Royce's theory to be roughly sketched. "An Idea is any state of mind that has a conscious meaning." In reference to meaning, logicians have never failed to recognize "quod fere in omnium ore celebre est, aliud scilicet esse quod appellative [*i.e.*, adjectives] *significant*, et aliud esse quod *nominant*. Nominantur sigularia, sed universalia significantur." So John of Salisbury, Abelard's pupil, expresses the distinction. That for the most important signs the signification is intrinsic, the denotation (*quod nominant*) extrinsic, is generally recognized. Professor Royce marks the distinction by the terms Internal Meaning and External Meaning. He conceives of the internal meaning in a special way. Another writer, a quarter of a century ago, proposed this maxim: "Consider what effects that might conceivably have

practical bearings we conceive the object of our conception to have. Then our conception of those effects is the *whole* of our conception of the object." Carrying this pragmatistic spirit a trifle further, Professor Royce holds that the internal meaning of an idea is a Purpose, instead of regarding it, with his predecessor, as a germinal purpose. This purpose – obscurely recognized, since not all to which it will lead is foreseen; partially fulfilled in being recognized, since a purpose strives first of all to understand itself; but mainly unfulfilled, since it would not remain a purpose after fulfilment – is the internal meaning, or signification, or depth, of the idea. The purpose is vague – anything that refers to the future is more or less vague; and a sincere purpose to do a thing "right now" actually does it. The purpose is to do a thing under certain circumstances. Completely to define these circumstances, it would be necessary to give a biography of the purposer from birth, without any omission. The purpose is to do something in order to produce certain results. Completely to define the result accomplished must involve a complete representation of the agent's future life. In short, the complete fulfilment of any purpose, which alone is the external meaning of the idea, is no less than the entire life of the thinker. The reviewer will say, for clearness, that neither these nor the majority of the author's positions have been satisfactorily shown to be true (in the reviewer's opinion, but the author holds them to be perfectly demonstrated). The principal of them may rank as verifiable hypotheses possessed of the plausibility and other qualifications that render them eminently worthy of further examination, even if an engine of rare usefulness must be drawn away from other work for the purpose.

That the object of an idea, then, its external meaning, is of the nature of a sign could hardly be gainsaid. But Professor Royce finds it not only a sign but an idea; not only one idea but a "concrete" idea in the Hegelian sense, and that, not relatively, but perfectly, and so of the nature of life; and not only life, but an entire life. "The Being of the real object of which you now think, means a life that expresses the fulfilment of just your present plan."

But suppose the reader to ask, How can an idea, so microscopic a piece of a life, contain within its implication a distinct feature corresponding to every feature of the entire life of which it is only a part? This difficulty is happily removed by the author in a way which ought to be instructive to those metaphysicians whose horizon is limited by the walls of a theological seminary. He resorts to Gauss's conception of an *Abbild*, which has played a great role in mathematics. That is to say, he likens the idea representing the entire life to a map of a country lying upon the territory of that country. Imagine a map of England, absolutely perfect in its minutest details, to lie upon the soil of England, without covering the entire country it maps. Upon this map would be shown the very ground where the map lies, and the map itself, in all its minutest details. In this map of the map, the map will be shown again; and so on endlessly. Here, then, will be a part fully representing its

whole, just as the implicit meaning of the idea is supposed to represent the entire life. It is to be noticed that, each successive map lying well inside the one which it immediately represents, unless there be a hole in the country which a ringshaped map encloses, the endless series of maps will converge to a single point, which represents itself throughout each and every map of the series. In the case of the idea, that point would be the self-consciousness of the idea. An idea, being a state of mind with a conscious purpose, must evidently be self-conscious.

There, then, would seem to be a beautiful and a needed (though not a complete) confirmation of the aptness of the metaphor. Yet here the author recoils, and refuses to admit the continuity, or even the analytic continuity, of the map. He insists that no representation represents itself; a hard saying, which exact logic appears directly to refute. "The world of Self," he says, "whatever continuity of internal structure it may, in some aspects, possess, is, in its principal form of expression, embodied in a discrete series of ... individual expression.... Experience at any moment shows how I am conscious of my ... approaches to selfhood in any way in the form of a discrete series in which one stage ... is followed by the next." The argument which supports this assertion is not assented to upon all hands. If it be true, there are but two alternatives: either, notwithstanding this, in the respects in which an idea represents an entire life there is continuity, or, at least, a higher infinity than that of the simple endless series; or else the doctrine that to an idea a reality must in some shape correspond must fall to the ground.

According to Professor Royce, an idea fails of being a Self only because it is general and not perfectly determined; which the reader may deem a dark saying unless the sword of Hegel is invoked to cut the knot. Its implicit or germinal inward meaning would, then, be a little Self, representing the entire life as its external meaning. In a similar way, the Self of the man is perhaps included within a larger Self of the community. On the other hand, the man's Self encloses intermediate selves – the domestic Self, the business Self, the better Self, the evil spirit that sometimes usurps his sovereignty. Of course, the system of delineation for the larger and for the enclosed selves will be different. Here the author draws support from the psychological doctrine of what he calls the "time-span," a doctrine which, so far as it has really been placed beyond important doubt, amounts to little more than that our image of the events of the few seconds last past is, or is very like, a direct perception, while our representation of what happened a minute or so ago is relatively of a far more mediate character. This phenomenon had already been seized upon by several idealistic writers as affording a refutation of dualism; but there is no better way of appreciating the large calibre of Royce's thought than by comparing their styles of putting this idea to the service of metaphysics with his. He imagines that the greater selves will naturally have vastly longer time-spans than the lesser selves. Now a consciousness whose time-span, or

"specious present," or "empirical present," as it is variously called, was a thousandth of a second or a thousand years would not ordinarily be recognized as a consciousness at all by a human observer of its external manifestations. The time-span of the All-enclosing Self must cover all time; and this gives a sort of support to the imagination if we wish to reconcile foreknowledge and free will after the manner of Boëthius, St. Augustine, and others.

Every reality, then, is a Self, and the selves are intimately connected, as if they formed a continuum. Each one is, so to say, a delineation; with mathematical truth we may say, incongruous though the metaphor is, that each is a quasi-map of the entire field of all the selves, which organic aggregate is itself a Self, the Absolute Idea of Hegel. So far as a philosophical conception can be identified with God it is God.

All reasoning goes upon the assumption that there is a true answer to whatever question may be under discussion, which answer cannot be rendered false by anything that the disputants may say or think about it; and further, that the denial of that true answer is false. This makes an apparent difficulty for idealism. For if all reality is of the nature of an actual idea, there seems to be no room for possibility or any lower mode than actuality, among the categories of being. (Hegel includes modality only in his Subjective Logic.) But what, then, can be the mode of being of a representation or meaning unequivocally false? For Hegel, the false is the bad, that which is out of harmony with its own essence; and since, in his view, contradiction is the great form of activity of the world, he has no difficulty in admitting that an idea may be out of harmony with itself. Prof. Royce, however, seems almost to resent the idea that anybody could suppose that he denied the validity of the distinction of truth and falsehood. He is fairly outspoken in pronouncing sundry doctrines false (a word Hegel hardly uses), even if we do not quite hear his foot come down; and nothing does he hold more false than the usual form of stating the distinction now in question, namely, that a true proposition corresponds to a *real matter of fact*, by which is meant a state of things, definite and individual, which *does not consist merely in being represented (in any particular representation) to be as it is*. For example, if I dream that I find I can float in the air, this matter of dream is not matter of fact, for the reason that the only sense in which I can float in the air is that so my dream represented the matter. Now Prof. Royce offers to demonstrate by necessary reasoning that the statement – or, as he expresses it, that "to be real means to be independent of ideas which relate to that being" – is false. His argument to this effect will serve as a sufficiently characteristic, but rather favorable sample of his general style of argumentation.

Having given us to understand that he is going to disprove the proposition, he opens his argumentation by declaring that he does not know what the proposition means. Thereupon, he proceeds to propound a general maxim of procedure for all cases in which one has to refute a proposition without

knowing what it means. It is to begin by assigning to it its "most extreme form." This certainly does not signify the most extremely defensible meaning, but rather the most extremely indefensible meaning that the language will bear. The proposition having been refuted in this extreme sense, it will only be necessary afterwards to argue that other interpretations make no essential difference. This maxim, one would suppose, would prove very serviceable to anybody who should have any large amount of that sort of refutation to perform. In accordance with this maxim, Prof. Royce begins by assuming that realists hold that no idea in the slightest degree determines the real object of it, whether causally or in any other manner. Whether this does not overstep the limits of admissible interpretation, seeing that a realist who meant this would deny that any promise can really be kept, or that any purpose can influence the real result, the reader must say. At any rate, it would not seem to be a difficult position to refute.

Now in order that he may get the realist where he wants him, there are two acknowledgments which Professor Royce endeavors to extort from him. To bring him to the first, the author assumes the principle that all causal action is reciprocal, or of the nature of reaction. This is evidently contrary to popular opinion, which holds that while the past has exerted some efficient causality upon the future, the future cannot have any *effect*, in the strict sense of that word, upon the past; and that while the future may have influenced the past by final, or ideal, causation, the past cannot possibly influence the future as the aim of the future. The reader may judge whether a realist of so extreme a type as that which Professor Royce has set up would or would not admit that the real object of an idea cannot have influenced the idea, in the absence of any attempt on the part of Professor Royce to prove his general principle of reciprocity. If he would not, old-fashioned logic (which Hegelians, it is true, hold in high contempt) would pronounce the attempted demonstration to be a bald *petitio principii*.

In order to extract the second acknowledgment from the realist, Professor Royce produces an argument which would seem to have as much force for one kind of realist as for another. He supposes two objects, B and R, to be related to one another as the realist supposes the Being, or the real object of an idea, and the Representation, in the form of an idea of that object, to be related; and he undertakes to define the relation between them. "The definition in question," he says, "is, as a mere abstract statement, easy." One would think so. The realist simply says that B is not constituted by its being represented in R; that is, he says that the fact that B is as it is, would be logically consistent with R's representing it to be otherwise. But in place of this easily comprehensible relation, what fantastic attempt do we find at the definition that was pronounced to be so easy! Professor Royce will have it that the realist holds that the relation is such that no matter how R may be metamorphosed, it is logically possible for B to remain unchanged. In such a sense, what two

things in the world are independent? Change the problematic madness of Hamlet into the pacification of the Philippines, and it will become logically inconsistent with the continuance of great disturbances there. But change the doubtful *representation* by Shakspere that the fictitious Hamlet was unhinged into the *representation* that the Philippines were pacificated in 1901, and it will not have the slightest logical consequence for the real state of things. The truth is, that Professor Royce is blind to a fact which all ordinary people will see plainly enough; that the essence of the realist's opinion is that it is one thing to *be* and another thing to *be represented*; and the cause of this cecity is that the Professor is completely immersed in his absolute idealism, which precisely consists in denying that distinction. It is his element, and there is total reflection at its surface. That, however, is what Professor Royce asks the realist to admit as a premise. The conclusion which he deduces from it is that if B is linked as cause to any determination of R, there must be a *tertium quid* by the mediation of which the causation takes place. Now the premise is absurd; and the formal rule is that from an absurd premise every conclusion must be allowed to be logical; that is to say, it is needless to dispute its logicality, the premise being false. The argument, therefore, cannot be called formally bad; nor can we object that a few lines below, in a restatement of the conclusion, B's being linked as cause gets changed into B's having any causal *or other* linkage.

Professor Royce, armed with his wrong definition of realism, goes on to a dilemma to show that, whether the realist says that real things are one or are many, he equally involves himself in contradiction. But, although the characteristics of his style of argumentation become even more prominent in that dilemma, the exigencies of space forbid our following him further. But we should like to say one word to this powerful and accurate thinker who has been so completely led astray in his argumentation by his Hegelian logic: Absolute idealism depends, as Hegel saw that it did, upon assuming that position at the outset. If your refutation of realism is addressed to students who are already absolute idealists at heart, we will not undertake to say whether it will be serviceable for the development of that doctrine, or not. But if it is addressed to realists themselves, it must conform to the logical principles recognized by realists, or be nugatory. Now you know very well that realists do not admit that matter of fact can be apodeictically demonstrated. You ought to know, and surely you do know, that if you drive them into a corner, they will simply modify their admissions so far as may be necessary to avoid self-contradiction, and that from the very nature of apodeictic proof it is absolutely impossible to close off such escape in arguing about matter of fact. The history of the doctrine of parallels illustrates what logic shows to be necessarily the state of the case. But the question of realism is a question of hard fact, if ever there was a hard fact; and therefore your method must be revolutionized if you are ever to convince any master of logic.

A REPLY TO PROFESSOR ROYCE'S CRITIQUE OF INSTRUMENTALISM

John Dewey. "A Reply to Professor Royce's Critique of Instrumentalism." *Philosophical Review* 21.1 (January 1912): 69–81.

The republication by Professor Royce of his important address at the International Congress of Philosophy at Heidelberg, upon the Problem of Truth,[1] will set many persons to reviewing the problem, and some, perhaps, to considering it for the first time. Its criticisms of the instrumentalist position are so searching and its statements of that position so eminently fair – that is to say, intelligent – that, as one of those expounded and criticized, I should feel at once professionally stupid and personally unappreciative if I made no effort at response. I shall not attempt, however, to traverse the entire field but shall, in the main, confine myself to one point which Professor Royce has made peculiarly his own: The indispensableness to the instrumentalist theories of truth, even as working empirical theories, of a recognition of the social implications of ideas and beliefs. This indispensableness appears, to Professor Royce, fatal to the instrumental conception; to me it seems its essence.

In gist, Mr. Royce contends that if one admits the instrumental conception to be sound "as far as it goes," one is thereby bound to go a good deal farther – all the way to absolutism. Or, in his own words:

> Instrumentalism, consequently, expresses no motive which by itself alone is adequate to constitute any theory of truth. And yet, as I have pointed out, I doubt not that instrumentalism gives such a substantially true account of man's natural functions as a truth seeker. Only the sense in which instrumentalism is a true account of human life is opposed to the adequacy of its own definition of truth.[2]

There is a sense in which – so Professor Royce repeatedly states – instrumentalism is (or better, "contains") a correct "report of the truth about our actual human life, and about the sense in which we all seek and test and strive

[1] *William James, and Other Essays*, Essay IV. New York, 1911.

[2] P. 222 [this volume, p. ??].

for truth, precisely in so far as truth-seeking is indeed a part of our present organic activities."[3]

It is obvious (is it not?) that when a criticism is made from the standpoint of the acceptance of a certain conception, and when the critical procedure tries to show that acceptance in logical good faith is quite incompatible with the version of the conception bruited abroad by those most actively engaged in circulating it, it is then obvious, I say, that everything depends upon *what* meaning is attributed to the conception that one accepts, upon *how* one conceives the conception that he announces himself as accepting. *If* the conception of instrumentalism that is "accepted" is after all one's own conception rather than that of those who hold the definition of truth in question, what one has demonstrated at the end is that one's *own* conception of instrumentalism is logically compatible only with absolutism – a conclusion not entirely surprising at the hands of such an accomplished dialectician as Professor Royce.

My first task, accordingly, is a churlish one. I have to show that the logical success of Professor Royce consists in attributing to the instrumentalist certain ideas which are indeed Mr. Royce's own presuppositions, but which are quite foreign – in fact and in logic – to the instrumentalist's position. In short, Professor Royce has not, after all, adequately "accepted" the instrumentalist account even as an empirical account of truth-seeking and truth-testing, for in accepting it he has read into it things so obvious, so self-evident to him that it has not occurred to him that the instrumentalist makes his way, for better or worse, precisely and only because he has rejected and eliminated them. I call this task churlish. And so it is. When one considers how often the pragmatist and instrumentalist have been refuted by denying to them any vestige of sense, to say nothing of truth, how often they have been refuted by attributing to them wilful perversity of facts evident to any sane apprehension, it would be a grateful task to acknowledge the sympathetic and just version – *in every point save one only* – of instrumentalism rendered by Professor Royce. But alas for one's natural piety; for present purposes it is just this one point that enters into the reckoning.

I

Let me quote at length a statement which an instrumentalist at once recognizes to be a sympathetic and just (if not complete) version of his own intention.

[3] P. 218 [this volume, p. ??].

> Human opinions, judgments, ideas, are part of the effort of a live creature to adapt himself to his natural world. Ideas and beliefs are, in a word, organic functions. And truth ... is a certain value belonging to such ideas.[4] But this value itself is simply like the value which any natural organic function possesses. Ideas and opinions are instruments whose use lies in the fact that, if they are the right ones, they preserve life and render life stable. Their existence is due to the same natural causes that are represented in our whole organic evolution. Accordingly, assertions or ideas are true in proportion as they accomplish this biological and psychological function. This value of truth is itself a biological and psychological value. The true ideas are the ones which adapt us for life as human beings.[5]

Alas, for that little – or big – word "psychological." How great, indeed, are the oaks that little acorns start; what a cataract the little crack in the dam finally lets through – and like samples of proverbial philosophy! Surely the unprejudiced reader would infer from the above statement that, though the term psychological is undefined, the criterion for its definition lies in the conceptions of "life," of "organic functions," of "adaptation to [better *in*] a natural world." And the inference would correctly represent the point of view of the instrumentalist. But, as Professor Royce proceeds, "psychological" is employed to designate the merely private, the merely personal, and, at times, even the internal, transient "states of consciousness." Then the "psychological" swells and swells, till it swallows up the "live creature," the "natural world" and "biological functions." And if the instrumentalist wants them back (and he must get them back if he is to carry on his business) he must go to the Absolute to take out a license.

The instrumentalist

> account of human organic and psychological functions may be – yes, is – as far as it goes true. But if it is true at all, then it is true as an account of the characters actually common to the experience of a vast number of men. It is true, if at all, as a report of the objective totality of facts which we call human experience. It is true, then, in a sense which no man can

[4] The omitted words are, "in so far as we men can recognize truth at all." The phrase thrown into an exposition made professedly from the standpoint of the instrumentalist is significant. Even Mr. Royce cannot wholly free himself from the notion that instrumentalism's account of truth is a statement of what truth is "for us" as distinct from some absolute truth or truth for itself. Of course, from its own standpoint, it is a statement about truth, about the sole intelligible meaning of the term truth.

[5] P. 193–194 [this volume, p. ??].

> ever test by the empirical success of his own ideas as his means of controlling his own experiences.... If instrumentalism is true, it is true as a report of facts about the general course of history, of evolution, and of human experience – facts which transcend every individual man's experience, verifications and successes.[6]

The logic of this passage gives a narrow and exclusive sense to "individual man's experience," "his own ideas, his own experiences," a sense so narrow and exclusive as to throw between personal experience and "objective human experience" or the historic experience of the race, a gulf so deep and wide that only the Absolute *ex machina* will bridge it and bring the objective human experience and the individual's experience together.

The contrast is explicit in such a passage as the following:

> For no man experiences the success of any man but himself, or of any instruments but his own; and the truth, say, of Newton's theory consists, by hypothesis, in the perfectly objective fact that generations of men have really succeeded in guiding their experience by this theory. But that this is a fact no man, as an individual man, ever has experienced or will experience under human conditions.[7]

Here we have the logic exposed. Men are individuals; therefore whatever is experienced is one's own individual experience; or, individuals experience only themselves, and their exclusive possessions, which are, in fact, parts of themselves. The ground I plow is my own ground; I plow it with my own instrument, my own plow; the harvest – the success – is my own. Therefore the ground was never anybody else's; it is impossible for me even to see from it any other person's land (unless I secure a transcendental telescope); it is impossible for my plow to plow other persons' land; and the harvest, being mine, must be mine only, and therefore unsharable by others.

To my mind there is just one interesting question about such a view as this of the "individual" and of "his own" – the historic question. What ever led intelligent human beings to such a conception of human individuality and of its acts and states? What led to the identification of the individual with the private, and of the private with the merely private, with the absolutely exclusive and isolated? We are not now concerned however with a question of fact, but with a question of logic. Only as he assumes that the instrumentalist does and must presuppose this monopolistic, all-swallowing octopus of

[6] Pp. 221–222 [this volume, p. ??].

[7] Pp. 220–221 [this volume, p. ??]. Yet Professor Royce, an individual man, knows this objective fact!

an individual and "his own," does Professor Royce "accept" the instrumentalist account, and argue to its necessary implication of the Absolute. Speaking for myself, I may say that if I had any such nihilistic, anarchistically egoistic notion of the individual man, of his doings, states, tools and results, I should probably be willing to resort to an absolute to escape my "own" awful isolation and selfishness. For selfishness is agreeable only when it involves others. But even so, such atrophied logical sense as may be supposed to survive even in an instrumentalist would haunt me with a suspicion that this Absolute was but another of my purely personal belongings, the most precious of my private possessions in appearance, and, in fact, a huge joke that some peculiarly private part of my private being was working off on my more accessible private properties. For, to consider the matter logically, it is passing strange that the private nature of my experience makes it impossible for me to be aware of such a prosaically limited matter as the existence of Sir Isaac Newton while it absolutely warrants the absolute truth of my belief in something which includes Sir Isaac Newton along with everything else past, present and future. Surely the proverb concerning straining at a gnat and swallowing a camel should be brought down to date.

But we are getting too far away from the instrumentalist's position as he himself "accepts" or conceives it. Let us try, with a more unbiased sympathy, to take that point of view from which "human opinions, judgments, ideas, *are part of the effort of a live creature to adapt himself to his natural world*," where beliefs are organic functions, and experiences are organic adaptations involving such functions; and where the issue – the success or failure – of these adaptations constitutes the *value* of the beliefs in question. Is there any conceivable way in which a person who had adopted (with however moderate an understanding of what he was about) such a position could still hold that the natural world was merely his own idea; that a live creature was just one of his own private entertainments or conceits, and that organic functions in their tools and results were confined to his own insides?

It is not necessary to enter into a definition of "psychological" upon the basis of the instrumental conception. But it must be conceived in accordance with the fundamental position of the live creature adapting itself to a natural world. And one of the most rudimentary traits of a live creature is its continuity with a racial organic life, just as that of an environment is its spatial diversity and its temporal perdurance. Without these features, adaptation and organic function are the most empty sort of term. Follow out the implications of *such* conceptions instead of the conception which Mr. Royce holds (and with great and fatal generosity lends to the instrumentalist) and the gulf between the objective human experience and the supposedly purely subjective individual experience disappears. Life individuates itself, and particular individuations appear and disappear. But the individuation is a trait of life; it is not the mystery of a private, isolated somewhat which destroys all the

natural traits of life to replace them with its own quite opposite traits. We are not to interpret "life" in accord with some psychological preconception of the merely personal; we are to interpret the personal in accord with the functions of life. A particular passage may serve to bring out the difference of conception. After stating what the truth of the Newtonian conception would consist in from the instrumental point of view, Professor Royce goes on to ask about the sense in which the statement of the historic episode of the formation and success of Newton's theory is itself true. Unless the instrumentalist is quite stupid, he will, I take it, apply his own criterion. It is true by the same token; it enables predictions, it gives control, it facilitates intercourse, it clears the path of obscurities, it guides (instead of obstructing) new observations and reflections, it brings men together instead of dividing them – so far as it is acted upon and thus genuinely asserted. But this path seems to Professor Royce to be quite closed to the instrumentalist.

> Newton is dead. As mortal man he succeeds no longer. His ideas, as psychological functions, died with him. His earthly experiences ceased when death shut his eyes. Wherein consists to-day, then, the historical truth that Newton ever existed at all, or that the countless other men whom his theories are said to have guided ever lived, or experienced, or succeeded?

Such statements followed by such a question are well calculated to inspire one with a feeling of despair regarding the possibility of arriving at any philosophic understanding. Newton is dead; therefore how can I assert as truth that he ever lived? The obvious answer is so obvious and so easy that it cannot be relevant to what Mr. Royce has in mind: the answer, namely, that Newton cannot be dead unless he once lived, and that, organic life being what it is, if he lived in the seventeenth century, he is surely dead by this time. I cannot imagine any beliefs operating and succeeding as organic functions in the development of life unless such simple and ordinary beliefs as these are capable of working, and working with a reasonable degree of success. If the propositions were that Newton is dead, though he never lived; or that because he was living in the seventeenth century, he must be living now, I can see how the propositions would offer difficulties to a pragmatic theory; I confess I do not see how they could "work." Seriously, and not in levity, this seems to me the inevitable answer and the only answer that instrumental theory can make to the question just cited.

But equally I have no doubt this reply is quite irrelevant to what Professor Royce had in mind. And, accordingly, I shall have to make a guess as to what presuppositions underlie the question and address a reply also to them. There are a number of phrases in the discussion which lead me to infer that Professor Royce identifies truth with existence. Now if the truth about Sir Isaac Newton's existence is the same thing as that existence itself, it is quite sure

that no possible present experience will yield truth. For the working in experience of a belief or conception for its control, guidance, clarification, for social intimacy and emancipation, will not operate to raise Sir Isaac Newton *in propria persona* from the grave; it will not in short constitute (or reconstitute) his *existence*. But instrumentalism never pretended to encroach on the idealistic privilege of creating natural existences by formulating truths about them. It is content with the humbler task of describing how men do as matter of fact recreate, transform, *some* natural existence by intellectual formulations about *some other* existence. (The successful transformation of some things by use of intellectual formulations about other things being what instrumentalism calls the truth of these formulations.)

I know of no *a priori* compulsion to formulate conceptions or beliefs regarding Sir Isaac Newton; it is a safe guess for instance, that many an Oriental potentate has gone to his grave about whom no belief will ever be entertained, just as the vast majority of natural happenings go by without being reflected upon. But when there is a specific need for thinking, and a specific hypothesis emerges in response to the need, it is needful that we should have some way of testing its value, of developing it to the point of being true or false. And acting upon the hypothesis to select and collate data, to predict, to guide new observations and reflections, to organize the seemingly discrepant and to illuminate the hitherto obscure is the way. The success of the hypothesis upon and along this way is its truth.

If, however, the death of Sir Isaac Newton, and the cessation of his experiences, carried with them the absolute interruption of organic life, of all experience, if his experience, in other words, operated in absolute discontinuity in matter and method from mine and mine from yours, I can well see that the instrumentalist would be put to it to frame any idea about Newton, to say nothing of verifying it. But the difficulty would not be confined to the instrumentalist. Even the absolutist would, in such a situation, be unhelped by the Absolute. And if instrumentalist and absolutist alike do make judgments about Newton and, within certain degrees of approximation, arrive at successful outcomes, it is because life, experience, has its own continuities and sociable relationships.

And this brings me to my second guess about the difficulty which Professor Royce feels his question to involve. He presupposes, again, the completely egoistic, exclusive nature of Newton's experience – his life, his acts – on one side, and of mine on the other. "His ideas, as psychological functions, died with him." But did they? And if they did, what are we going to do about it, even with the help of the conception of the Absolute? For so far as they "died with him," the problem is not that of some eventual verification of our ideas about his ideas, but of our having any idea about his ideas.

In short, we come again to our basic statements: one about the instrumentalist, the other about Professor Royce's position. (a) By calling Newton's

idea, his theory, a *function*, instrumentalism means to emphasize precisely that it *was* a function – to insist upon the need of reinterpreting the adjective "psychological" from the standpoint of function – an organizing and organized act, public, objective, impersonal just as surely as private, individual, personal. Certain images, a certain emotional tone of inward landscape, may be said to have "died" when Newton died. But to say that his idea of gravitation, as a vital *function*, died with him is to traverse the facts. Newton acted through it, lived it out, so adequately, that it became an integral part of the activities of educated men and scientific inquirers throughout the civilized world. Since this transmissive operation is just one of the things that is included in the conception of "success" of a vital function, one is not accepting the standpoint of instrumentalism when one conceives the vital function as something which renders impossible this transmissive operation. That the idea was made true means precisely that as a *function* it did not die.

(b) As to the logic of Professor Royce's own conception. Professor Royce says of certain statements about Newton: "No doubt all these historical and socially significant statements of mine are indeed substantially true" (p. 219 [this volume, p. ??]). Professor Royce would doubtless also hold that there is a countless multitude of doings and sufferings of Newton about which we cannot now make any intelligible statements. So far as the "substantially true statements" are concerned, does not Professor Royce (and everybody else) fall back upon the procedure of which instrumentalism is simply a generalized description? And as far as the other to us non-existent "truths"[8] are concerned, does the conception (or the Being) of the Absolute help us one bit? Upon the Absolutist theory, what explanation can account for this partiality on the part of the Absolute? Why has it rendered certain events so opaque and silent and others so transparent and communicative? Is there any explanation that does not take us back to the instrumentalist terms – terms of vital doing under conditions of natural and social need, adaptation and success?

And so far as our belief in the existence of the Absolute is concerned, why should we adopt a different logical procedure from that which has brought us to believe certain things about Newton? If the continuities, the transmissive bearings of life, of experience, suffice in the case of Newton to enable certain intellectual formulations – reflections – to prosper while dooming others to defeat, why, if the Absolute exists, should we not, *a fortiori*, wait till conditions have made the conception of its existence one that works out under tests? And, lacking these instrumental tests, what right have we to assert the truth of what, by Mr. Royce's own hypothesis, is a purely private, personal idea?[9]

[8] Not "truths," but events, on any except a preordained idealistic basis.

[9] "Instrumentalism in so far correctly defines the nature which truth possesses *in so far as we ever actually verify truth*," p. 224 [this volume, p. ??] (italics mine).

II

As respects certain truths, some instrumentalists – Professor James particularly – have made much of the significance of vicarious social verification. In Mr. Royce's words:

> Since we are social beings, and beings with countless and varied needs, we constantly define and accept as valid very numerous ideas and opinions whose truth we do not hope personally to verify.... If we personally do not verify a given idea, we can still accept it then upon its credit value. We can accept it precisely as paper, which cannot now be cashed, is accepted by one who regards that paper as, for a given purpose, or to a given extent equivalent to cash.[10]

This procedure Professor Royce accepts as an actual procedure, while he holds that reliance upon it is inconsistent with the instrumental conception of truth, – that, consistently, instrumentalism must identify the act of giving credit with truth itself, that is to say, anything is true to which we find it expedient to give credence at a given moment. Mr. Royce disclaims being an intellectualist of the rationalistic type, but he employs the good old rationalistic device of rigid alternatives. Either the assertion which I accept on credit *is* already true (truth belongs to the assertion anyway) or else by its truth I mean simply that I give credit to it. The former alternative surrenders instrumentalism; the latter puts it in the position of making truths offhand, while you wait – the sanctioning of caprice, whim, etc.

For reasons which I hope will appear presently, I am particularly interested in the implications of the "credit" notion with respect to its content. Before dealing with this phase of the matter, it seems necessary, however, to devote space to the formal dilemma. Upon close inspection it will be found, I think, to resemble most cases of formal alternatives in philosophic discussion. Two extremes are set up as exhaustive, while as matter of fact multitudes of other alternatives glide freely through wide-open intervening meshes. What *should* it mean upon the instrumental theory to accept some view or idea as true upon social credit? Clearly that such an acceptance itself works. And if the environment, the medium of action, be social could any other method save that of accrediting the results of experience in others be expected to work? There is nothing so licentious about the matter as Professor Royce's abstract logic would make out; the acceptance upon credit is subject to precisely the same sort of tests – of working under conditions – as acceptance on the basis of more direct personal verifications. What is indicated is that the social medium of life is as continuous as we have seen life itself to be. One has

[10] Pp. 224–225 [this volume, p. ??].

verified in innumerable cases that under certain conditions one can trust to the experience and the reports of others; one has found out that the limits between one's own experience and that of another are quite arbitrary and elusive. Besides this general verificational background, there is the specific verification, through working, of *acceptance* of this particular belief upon the credit and authority of some particular group of persons. And besides, there is frequent verification through the experiences of others who have given credit to these assertions – a method which could be made to appear vicious by the logic of abstractionism, but which, in inductive logic, is independently cumulative and hence confirming. In short, one doesn't, as an instrumentalist, accept arbitrarily on credit; he accepts on probation, hypothetically, just as one accepts his own hypotheses when they first occur to him. As this acceptance is confirmed by his works, the acceptance becomes a genuine accrediting; it has received the kind of trying by experimental tests in life that the conditions permit. That this is the way in which sensible men proceed can be shown by an argument *ad hominem*, indicating that even an absolutist must *actually* so proceed. Let us admit with Professor Royce that to the assertion in question truth or falsity already inherently belongs. Now, being unable to verify the matter directly, what shall be my attitude? I cannot, by hypothesis (Professor Royce's own hypothesis), be sure whether it is true or false, although I am sure it is already either one or the other. According to Professor Royce the only recourse possible is to accept or reject, just arbitrarily, by whim, by what seems agreeable at the moment. In short, the dilemma is one which applies only to those who hold Mr. Royce's view, and for them it takes the form of a choice of the two alternatives: Complete scepticism as to what is the truth or falsity of most things in history and nature, or else the loosest go-as-you-please most wayward opinionatedness. Other people employ the cautious testing of the kind and amount of credit to be given to others' ideas and reports that is described in the instrumentalist account.

As I have already stated, I find my significant interest attaching to the conception of social credit, and to the implied analogy of belief with credit in business, for this suggests that my *personal* experience is itself social in origin, matter and outlook. In good business, it is intimated, there is some value behind the *credit*; namely, in the philosophic analogy, truth. In purely speculative business, on the contrary, there is nothing but credit behind the credit: the instrumental theory of truth in the philosophic analogy. Now that business, modern business, is done so largely on credit seems to me a significant fact, and one which is peculiarly important for the instrumental theory. For so far as modern business proceeds upon a credit basis, it does *not* rely upon equating credits to values preexisting; modern manufacturing and commerce would go into wholesale bankruptcy were such its basis. It proceeds upon the basis of the *potentialities* of what already exists, upon the *future* operation of industry, good faith and consumption to realize these poten-

tialities. Only in times of panic is there a falling back upon the past, upon the already existent store. And the immediate effect of the insistence upon backing *from behind* of already extant values is to restrict business. There must, indeed, be something behind – fields, woods, mines, human labor, human intercourse, mutual trust, desires, etc. But the credit is not measured by them – not by them just as back there, behind. It is measured by an anticipated future use of them. It is not a matter of their being there in a finished state; it is a matter of their expected consequences, when something is done to them and with them. Credit operates for the more effective and varied use of what is there; not to reduplicate it in some parallel series. And it is the outcome, the actual consequence, that confirms or condemns any particular giving of credit.

I have no wish to base conclusions or theories on a possible analogy. I do wish, however, to secure its full suggestive force. Credit exhibits a possible future outcome operating as present factor to guide and enrich the conditions whose possibilities it relies upon. So does intelligence. Both involve a risk, an uncertain speculative element; both involve, therefore, the need of check and test, of responsibility to the achievement of ends, the production of consequences. Both involve something "behind" them, prior existences; but neither of them is a reiteration or reinstatement of the prior; both are concerned with the potentialities of things, and take effect in endeavor to make potentialities real. And as credit is distinctly a social phenomenon, so is the accrediting which marks the life of thought. Social verification is not, taken by and large, a *pis aller*, in default of "personal" verification. It, and it alone, is verification; personal verification is but a step on this social road – an encouragement, an authorization to go ahead. Experience, life – just as is that phase of experience called business – is social, and it exhibits this sociability nowhere more than in the continuity, the interpenetration, the reciprocal reinforcement of meanings and beliefs. Instead of an Absolute being required to substantiate this social phase of the life of intelligence it is much more probable that the Absolute is a somewhat barren and dry isolation and hypostatizing of the everyday sociality of experience. The accrediting of others' experience is the fact that our personal experience is so much other and more than the narrow personal private matter upon whose "acceptance" Mr. Royce founds his dilemma.

If then, I were to try to gather together the significant strands of instrumentalism in opposition to Professor Royce's welcome of it as a convenient road to absolutism, I should say that as method for philosophy it indicated a more severe intellectual conscience; less free and easy use of the concept of Truth in general and more careful use of truths in particular to designate such conceptions and propositions as have emerged successfully from the test conditions that are practically appropriate. In substance, as distinct from form or method, I should say it meant recognition of intelligence as the way in

which future possible consequences became effective in the present – the recognition of real time and real potentiality – and a recognition of the utterly false character of the prevailing notion of the sheer privacy, the egotistic isolation, of experience, of conscious life. The case is immensely understated when we restrict ourselves to the possibility of pragmatic verification of acceptance of beliefs on credit from others – adequate as is the noting of this possibility for the purpose of securing exemption from Professor Royce's dilemma. The fact is that the life, the experience (including the organic acts of ideas, opinions, judgments, etc.) of "individual man" is already saturated, thoroughly interpenetrated, with social inheritances and references. Education, language and other means of communication are infinitely more important categories of knowledge than any of those exploited by absolutists. And as soon as the methodological battle of instrumentalism is won – as it will be, not by instrumentalists, but by the constantly increasing influence of scientific method upon the imagination of the philosopher – the two services that will stand to the credit of instrumentalism will be calling attention first, to the connection of intelligence with a genuine future, and, second, to the social constitution of personal, even of private, experience, above all of any experience that has assumed the knowledge-form.

THE PROBLEM OF KNOWLEDGE

Douglas C. Macintosh. "Royce and Boodin." Selection from *The Problem of Knowledge* (New York: Macmillan, 1915), chap. 17, pp. 384–390, 395–396.

We shall have to examine the views of one more representative of idealistic absolute intellectualism, viz. Josiah Royce; for, in spite of his "absolute pragmatism,"[1] this philosopher's theory of truth remains, as we will endeavor to show, essentially intellectualistic rather than pragmatic. Royce makes many concessions to the pragmatist, although, as we shall see, they all fall short of essential pragmatism. He admits that every judgment is a reaction at a particular time to an empirically given situation, a reaction expressing, and determined by, the consciousness of a need to get control over the situation. He also admits that even the most remote speculations are, for the man who engages in them, modes of conduct, and that the thinker's ideas are his own deeds, or at least his plans of action.[2] But while maintaining that every opinion is a deed, intended to guide other deeds, and consequently that all truth is practical,[3] he does not propose to take this practical characteristic of truth as furnishing, under any conditions, a criterion of truth; he adopts a criterion and definition of truth which are, as will appear, quite non-pragmatic.

But even more important for the understanding of Royce's theory of truth than his relations to pragmatism is his rejection of realism. His fallacious arguments for a non-realistic system we have already examined, but his criticism of realism is almost equally open to objection. Even in his first published volume, on the ground that, as he alleges, common sense does not know what error is, he says, "Let common sense not disturb us, then, in our further search."[4] Against this summary procedure it is sufficient to remark that if common sense, *without the pragmatic criterion*, is unable to say what error is, it does not follow that common sense, *with* the pragmatic criterion, might not be able to furnish the desired solution. Moreover, in his treatment

of realism, Royce commits the fallacy of assuming that the refutation of a particular type of realism – and that a very extreme and indefensible kind – is a sufficient refutation of all realism. He assumes that realism must be absolutely dualistic in epistemology, completely sundering the *what* from the *that*,[5] and even supposing that what one mentally constructs and discovers as thus constructed, existed prior to that construction.[6] He also assumes that "independently real" must mean not only real independently of the knowledge relation, but real independently of *all* relations, a pluralism so absolute as to deny that there obtain among real things any relations except such as are so absolutely external that they are not *relations* at all.[7] It is small wonder, then, that a seeming triumph for idealism is easily obtained.

Having thus, as he supposes, shown the impossibility of a rational defense of realism, the need of finding some way of reaching objectivity becomes imperative. We need to hold that the subject of our judgments is Reality, not our idea,[8] and we need that the judgments which we need for practical purposes be also true of this reality which is not our idea.[9] What Royce proposes in this situation, as a substitute for realism, is to fall back upon what is given subjectively, viz, our needs;[10] and it is this private need of his own, as a non-realistic philosopher, this need of constructing objectivity out of our subjective needs, or of finding it in them, that explains his seemingly rather patronizing attitude toward contemporary pragmatism, with its emphasis upon the theoretical value of practical considerations. What we need in needing truth is, at the very least, according to Royce, companionship in our thinking,[11] but it is more than merely this.[12] The need of the moment needs to be controlled, not, as the realist imagines, by an independently existing object, but by "some universal expression of need – an expression that simply makes conscious what the need of the moment is trying, after all, to be."[13] Our need of truth is a need of an insight such as would remain invariant for every additional point of view;[14] and this, it is assumed, can only mean one's

own true self, including within its experience all possible points of view, and knowing that it includes them.[15] Thus we need, it is claimed, the Absolute Self, other than our present finite self, as an actually and eternally existent Judge, if we are to have truth.[16] Indeed, one's true Self, as such an Absolute Judge, must exist, if there is to *be* truth, whether known by any finite self or not; and this being so, there cannot be error,[17] or even ignorance,[18] without the true, all-inclusive Self as Absolute Judge.

Royce confesses that it is his voluntarism that is the secret of his absolutism;[19] but, in the light of what has been said, it would perhaps be truer to say that it is his provisional subjective idealism that drives him to take up voluntarism and to develop it in the direction of absolutism, a solipsism of the Absolute Self, as the only logical escape from a solipsism of the finite self. We "acknowledge" a transcendent, truth-knowing Absolute; we "define" the Eternal;[20] we "appeal to" an all-comprehending insight;[21] and the meaning of all this is that we *need* the belief in such an Absolute, and so we deliberately *take* it, not tentatively as a working hypothesis, as the pragmatist might do, but absolutely and outright, as if it were our indispensable possession.

Now it is true enough that, because we come to know things through experience, we naturally remember them as they were experienced, and imagine what we have not experienced as it would be, if experienced.[22] In this sense we do indeed appeal to experience, even when we refer beyond our own present experience. But what we must not forget is that what we intend to appeal to is not what the thing *is* experienced as, but what it *would be* experienced as, *if it were* experienced. The superhuman experience is, so far as these necessities of thought are concerned, simply a "regulative," not a "constitutive" concept. What the dogmatizing rationalist does, however, is

[22] What do I mean by the object of which I know that I am ignorant? Dewey would say, presumably, a future content of my own experience; and Royce, a present (or super-temporal) experience of the Absolute. But why "future"? Why "super-temporal"? Why "of the Absolute"? And why "experience"? What I mean is a *present reality*, of which, in some cases, *I* may have *future experience.*

to substitute for the "would be ... if," a simple "is," or an authoritative "must be"; and so deft is he in his logical legerdemain that his trick imposes even upon himself, and he concludes that the all-inclusive experience of the Absolute Self actually *is* and *must be*. It is true enough that something besides our subjective practical needs underlying our judgments is needed as the foundation and measure of their claim to truth; but what is needed is not necessarily superhuman truth – although we would not argue that there is none – but independently existing reality, accessible, under whatever conditions, to human experience and knowledge.

Royce, however, having rejected all such realism, and having consequently, after the fashion of logical idealists, confused the concept of truth with that of reality, is compelled to pursue the course we have just outlined. And in so doing, we must insist, while he still refuses the most essential and valuable element in current pragmatism, he acts upon, and really adopts in principle, the most logically vicious element in what we shall call pseudo-pragmatism.[23] Having first gotten himself, by a philosophical mistake, into unnecessary difficulties, he finds that the only thing that will save him from the necessity of retracing his steps and acknowledging the error of his ways is to assume the truth of an unverifiable proposition (that an Absolute, such as he depicts, exists); he therefore naturally "wills to believe" it, and immediately does so, arguing its certainty from its necessity, forgetting that the necessity is itself quite artificial and unnecessary. Royce criticises current pragmatism for its tendency to lapse into this pseudo-pragmatism *as a doctrine*, "identifying the truth of an assertion with one's own individual interest in making the assertion";[24] but he himself seems to have done the same thing, not in theory, but in practice. His "absolute pragmatism" is a necessary theoretical veil to hide the *absolute pseudo-pragmatism* of his actual procedure in this particular instance.

And what are the consequences of this making of agreement with the judgment of the absolute, all-knowing Judge the criterion of truth? Evidently, that even if we avoid Bradley's conclusion that we can never possess the truth, we are not able, logically, to say that we know that we have it, because the standard of measurement is inaccessible. The completely integrated experience of the Absolute the individual man never gets before him;[25] and since the only workings by which our assertions can be adequately judged are "their workings as experienced and estimated from the point of view of such a larger life,"[26] the agnostic conclusion is logically inevitable. In spite of the assertion

[23] See Ch. XVIII, *infra*.

[24] *William James and Other Essays*, p. 232 [this volume, p. ??].

[26] *Ibid*., p. 149 [this volume, p. ??].

that the Absolute Experience is the experience of my true self, it remains a fact that I, the finite self, do not experience it. And indeed Royce seems to admit that the knowledge we get, such as it is, by adopting his absolutistic criterion is a knowledge of our own ignorance.[27] And if attention be called to the fact that this completely agnostic conclusion is untenable and must be given up, it ought to be sufficiently obvious that this can only mean that the absolutistic doctrine of the criterion of human truth has been shown to be self-refuting.

But, strange as it may seem, Royce has no intention of making any such admission. Unlike Bradley, who consistently acknowledges the necessary inconsistency of his absolutistic position, Royce argues, against the logic of his position, that even he who has adopted the absolutist criterion can have absolute knowledge of absolute truth, because, as a matter of fact, he has such knowledge in all propositions which are such that to deny them is to assert them under a new form.[28] What he has overlooked here is the fact (as we would contend it is) that even these "absolute truths" are reached, not by the absolutistic, but by a humanistic criterion.

That in his own thinking he is really guided by some more workable principle than is to be found in his own theory is increasingly evident as we look further into his discussion of absolute truths. While it is claimed that in the realm of pure logic and pure mathematics absolute truths are accessible,[29] it is admitted that all such propositions are essentially hypothetical;[30] "absolute truth is not accessible to us in the empirical world."[31] And yet he seems to teach also that some absolute categorical truth concerning reality is derivable from these universal hypothetical truths. Hypothetical judgments, it is claimed, give us negative information about the real world,[32] and in the end they tell us indirectly what is, by telling us what is not.[33] Moreover, they give us positive and categorical absolute truth about the nature of the creative will that thinks the truth.[34] Indeed Royce seems to have intimations of a wider field of accessible absolute truths, when he says that, in view of the irrevo-

cableness of every past deed, every act of judgment that calls for a deed is irrevocably (and so, absolutely) true or false.[35] This last seems to be true only on the essentially pragmatic principle that judgments which satisfy every relevant practical purpose that ought to be considered (the purpose of the scientist, which is ultimately practical, being included) are really, and therefore absolutely, true; but this is very far from being consistent with Royce's absolutistic theory of the criterion of truth. Furthermore, much of the appearance of contradiction in the above-cited doctrines, first of the purely hypothetical character, and then of the essentially categorical character, of absolute truth, could be removed if only it were explicitly understood that this essentially pragmatic criterion might be employed. Universal truths are essentially hypothetical, until the conditions of the subject are included in the predicate, *sufficiently for all practical purposes which ought to be considered*; and then they become categorical. This *pragmatic absoluteness* of ordinary, humanly accessible, empirical truths, is the one thing needful to make Royce's "pragmatic absolutism" absolutely practical, and therefore presumably true. As it is, however, so far from his theory of truth being an absolute pragmatism, it remains at heart an absolute intellectualism.

* * *

J. E. Boodin's doctrine of truth is more pragmatic than that of other American realists. Not only does he contend that truth is sought from practical motives[36] and is instrumental;[37] even though he insists that the nature and test of truth[38] are not to be confused with the practical motive which leads to the seeking of it,[39] he offers, with reference to real objects, definitions of truth that are more pragmatic than intellectualistic.[40] His ideal for truth, however, seems to be intellectualistic. What thought really means, he says, is identification.[41] Truth, or the validity of an idea or belief, he defines as the agreement or tallying of that idea with its reality.[42] It is only because our description can never give the complete equivalent of real objects, and because so much of our

[42] *Ibid.*, pp. 210–211, 214, 234.

thought is merely symbolical, that he is forced, in certain cases, to go beyond this simple intellectualistic conception of truth.[43]

But when we consider that in typical judgment the subject is some real object, Boodin's would-be simple intellectualism and enforced pragmatism really signify the breakdown of the former theory. The attempt is made, however, to save a shred at least of intellectualism, when it is claimed that whenever our knowledge is concerned with social and ideal structures, it comes to share in the ideas it would represent, and so it is no longer *of* reality, but *is* reality. Its copying of the object is a reproducing of it; the knowing process, when it deals with psychological unities, *is* the nature of the object.[44] But at this point Boodin's thought does not quite accurately represent the facts. When the object of a knowing process is itself a knowing process, it is ordinarily not the same knowing process; and, as we have seen,[45] it is a much debated question whether there ever can be a knowing process which knows itself. Or, to speak logically rather than psychologically, in terms of ideas rather than in terms of knowing processes, even when B's judgment has for its subject A's whole judgment, then B's judgment, like all other judgments, must be to the intellectualist either tautologous or not quite true; for judgments, and even general facts of implication, are judged about by means of predicates which are themselves, as predicates, not facts but logical ideas, so that the relation of predicate to subject cannot be one of exact identity. But if what is meant is that B's judgment has for its subject the same reality as was taken as subject of A's judgment, and if B predicates of this same subject exactly the same idea (in the sense in which ideas of different persons can be the same) as A predicated, then B's judgment may be said to be identical with A's (except that it is B's rather than A's) ; but *the identity is not the truth*, for the supposed identity is not, like the relation we call truth, between the subject and the predicate of the judgment; it is between two judgments. It is thus found impracticable to deal in purely intellectualistic fashion with even the small corner of truth which Boodin has sought to reserve for such treatment.

VOLUNTARISM IN THE ROYCEAN PHILOSOPHY

John Dewey. "Voluntarism in the Roycean Philosophy." *Philosophical Review* 25.3 (May 1916): 245–254.

I am not about to inflict upon you a belated discovery that voluntarism is an integral factor in the Roycean theory of knowledge. Were it not obvious of itself, we have the emphatic utterances of Professor Royce himself in his address to this Association twelve years ago. Following a clue in that paper, it is my purpose to present some considerations relative to the relationship of voluntarism and intellectualism[1] in the earliest phase of Mr. Royce's published philosophy, thinking that the matter has historic interest and that it involves points relevant to forming a critical judgment of his later developments. Let me begin by quoting Mr. Royce upon his own early attitude. In 1881 he wrote a paper in which he "expressed a sincere desire to state the theory of truth wholly in terms of an interpretation of our judgments as present acknowledgments, since it made these judgments the embodiments of conscious attitudes that I then conceived to be essentially ethical and to be capable of no restatement in terms of any absolute warrant whatever." And, referring to his change of views in the last respect, he says: "I am still of the opinion that judging is an activity guided by essentially ethical motives. I still hold that, for any truth seeker, the object of his belief is also the object of his will to believe.... I still maintain that every intelligent soul, however weak or confused, recognizes no truth except that which intelligently embodies its own present purpose."[2] The statement is explicit. Taken in connection with the earlier position, it arouses curiosity as to the reasons for the transition from subordination of intellect to will to the reversed position.

I first turn to the paper of 1881.[3] The paper was one of the addresses at the Kantian centenary. Its title is, significantly, "Kant's Relation to Modern

[1] To avoid misunderstanding I would say that intellectualism is here used not in antithesis to empiricism or to sensationalism, but to denote any philosophy which treats the subject-matter of experience as primarily and fundamentally an object of cognition.

[2] *Philosophical Review*, Vol. XIII, p. 117 [this volume, pp. ?].

[3] *Journal of Speculative Philosophy*, Vol. XV, p. 360.

Philosophic Progress." It makes an attempt to assess, on one hand, certain contemporary movements in the light of Kant's critical principles, and, on the other hand, to indicate the ways in which Post-Kantian thought suggests a reform in Kant himself. The first part holds that Kant's criticism still bars the way to every attempt at a philosophical ontology. The ontological monism of Mind-stuff, of Panlogism,[4] of Alogism alike stand condemned as illegitimate excursions into ontological dogmas. The reforming portion centres about the Kantian dualism of sense and reason. The difficulty left over by Kant is clearly stated: A given category, say causality, is nothing unless applied to experience. But how can it be applicable? Only in case experience furnishes instances of uniform succession. But in that case, why the category? Thought is not needed. Or if it is said that it is necessary to introduce necessity, how about necessity? If sense experience doesn't justify it, then it too is futile. If it does, thought is superfluous. Either sense already conforms to order or else it is inexorably at odds with it. Now Royce's solution is, in brief, as follows. Sensuous, irresistible presence, presence wholly unquestionable, absolutely certain, is an ultimate fact: a datum. Spatiality (as had just been claimed by Professor James) exists also as just such a simple irresistible quale. Succession as instantaneous sequence is also such a datum. What thought, as essentially spontaneous, essentially active, does is to give the immediate momentary datum a reference beyond the present moment. However, the reference is not at first to an external cause. The primary reference is a time reference. In every cognitive act there is an assertion that the given data stand for, symbolize, recall, resemble, or otherwise relate to data that *were* real in an experience no longer existent. In short, thought primarily asserts or acknowledges the past. Then there is acknowledgment of the future: the synthesis of anticipation. Chief of all there is acknowledgment of other conscious beings than ourselves, acknowledgment of a universe of

[4] With respect to the problem of the evolution of Royce's later philosophy in its entirety, it is extremely important to note the ground for rejection of that Panlogism which was later accepted. It is connected with the fact of evolution. How can an Absolute Rational Whole change? How can it consist with progress from an earlier lower to a later higher? Or how can we think of every stage of the historical progress as itself a goal, when "the first starving family, or singed moth, or broken troth, or wasted effort, or wounded bird, is an indictment of the universal reason"? "Either evolution is a necessity ... and the Absolute must be conceived as in bonds, or else it is irrational and the Logos must be conceived as blundering." I call this ground of rejection extremely important, for surely the key-note of all Royce's later philosophy is the formulation of a way to combine the notion of the eternal moment with genuine struggle and defeat in time. The ethical connecting link in the *Religious Aspect* is the conviction that all genuine virtue or moral good exists at the point of overcoming evil. Hence the Absolute would be lacking in moral quality unless in its eternal changelessness it included and overcame the temptations and struggles of the finite and changing.

reality external to ourselves. Now "for the objects of these acts no possible theoretical evidence can be given more nearly ultimate than the one great fact that through acknowledgment and anticipation they are projected from the present moment into the past, future, and possible world of truth." And finally, "the goal of philosophy can be found only in an ethical philosophy. The ultimate justification of the act of projecting and acknowledging the world of truth constructed from sensible data must be found in the significance – *i.e.*, in the moral worth – of this activity itself." In short, the act of thought or judgment by which sense-data become a knowable world of objects and a world of other minds is itself an act, an affirmation of the spontaneity of consciousness. Hence it is impossible to get behind it intellectually or give it an absolute warranty: it has to be justified in terms of its own worth as an act, – that is to say, ethically.

The student of Royce's writings will see here certain ideas which are found in all his later writings: The acceptance of empirical sense-data as ultimate, things simply to be accepted as they are; the conception of them as intrinsically momentary, yet while including in themselves the fact of immediate or instantaneous sequence; the conviction that the problem of knowledge is, on the one hand, the problem of the temporal reference of these data, and, on the other, the problem of their reference to other minds, to orders of experience transcending our own; the belief that knowing is an act, an assertion, an acknowledging. Conjoined with them is the unfamiliar text that the active side, the voluntaristic and ethical side, is ultimate, and that no theoretical justification for it can be found. In his *Religious Aspect of Philosophy* published only four years later, we find established, however, the reversed relationship: we find set forth the Roycean all-inclusive thought which eternally realizes itself in all fragmentary and partial acts of will. From henceforth acts of will are not self-justifying. The ethical is transcended in the cognitive.

I make no pretense to tell how the change came about, in the sense of ability to reconstruct Mr. Royce's mental biography. There are, however, a number of indications of the *logical* sources of the change, which are found in the *Religious Aspect*; and to them I invite your attention. In the first place, the Fichtean tone of the acknowledgment in the first essay of the reality of other experiences, other wills, than our own is evident. It is not so much a bare fact that we acknowledge them, as it is a supreme moral duty to acknowledge them. Our natural, carnal acknowledgment is not of them as Experiences like our own but rather as factors which affect our own well-being: selfishness is the radical moral evil. This *motif*, implicit in the earlier document, is explicit in the *Religious Aspect*. But recognition of this fact brings with it the recognition of the reality of clash of wills, and of the need of an organization of wills or aims. To restate the treatment, rather than to try to paraphrase it, if my own cannot be the ultimate law for other wills neither can the will of any

other be the law of my will. There must be an inclusive organization which determines the aim of each alike. The same logic applies within one's own purposes; they too conflict and clash. Scepticism and pessimism are but the consciousness of this clash, in recognizing that amid plurality of aims there can be no ground for one making any one supreme, and no guarantee of abiding satisfaction. Moral certainty and moral confidence alike demand an organization of aims. Now such an organization cannot be itself an affair of will; it must be a matter of fact, a matter of reality or else of unreality, and hence something whose primary relationship is to knowledge. If it is valid, it is not because of anything in the "moral worth of the activity itself" or it is just that worth which is put in jeopardy by the conflict, the plurality, of wills. The moral worth of the will can be established only on the basis of an organized harmony of wills as an established fact. Whether such an organization exists or not is a matter of truth, of knowledge, not of volition. For if one say that one wills that such an organization exist, the dialectic recurs. This is but an individual will; an assertion of one will among many. And why should *its* assertion of an organization of wills be any better than any other assertion of bare will?

In his *Defence of Philosophic Doubt* Mr. Balfour[5] had stated expressly that preference for one ethical end over another must itself be a purely ethical matter – that is a matter of choice underivable from any theoretical judgment whether scientific or metaphysical. Each end founds a system of propositions all of which are logically coherent with one another. If revenge is an end-in-itself for me, then the proposition prescribing shooting a man from behind a hedge is a dependent ethical proposition belonging to that system. It is not knowledge but arbitrary choice which determines the end which fixes the dependent logical or theoretical system. It is fairly open to question whether such a conclusion does not follow from the principles set forth in Royce's earlier essay, when the clash of aims or acknowledging wills is taken into account. And, in the words of Mr. Royce, "The reader may ask: 'Is all this the loftiest idealism, or is it simply philosophic scepticism about the basis of ethics?'"

The moral will depends then upon an insight into a harmonious organization of all wills – an end in which pluralistic aims cease to be conflicting because they are taken up as elements into one inclusive aim. But does such an organization exist? This leads us to the discussion of knowledge and the criterion of truth. The conclusion is the absolutism of an all-comprehending eternal consciousness which has remained the central tenet of Mr. Royce's writings. "All reality must be present to the Unity of the Infinite Thought" (*Religious Aspect*, p. 433). "The possibility of an ontology and the supposed

[5] See *Religious Aspect*, Preface, and pp. 128–130.

nature of the ideal absolute knowledge" which, true to the spirit of Kant, Mr. Royce had denied in his earlier essay,[6] is now asserted as the sole way out of ethical scepticism. The transition to Absolutism is through (a) discovery of the scepticism latent in voluntarism when that is made ultimate; (b) the demand for a community of aims or organization of wills;[7] (c) the discovery that all recognition of ignorance and error, all sceptical doubt involves an appeal to a Judger or Thought which included both the original object and the original judgment about it. The analogy of such a comprehensive judger with the required moral organizations of wills which, in their separateness, clash, is obvious enough.

In being reduced to a secondary place, voluntarism is not, however, superseded. It persists, first, in the conception of the method of approach to Absolutism, and, secondly, within the conception of the Absolute itself. The first step out of the world of doubt is through the World of Postulates – a conception substantially identical with the acknowledging activity of the earlier essay. The external world may be regarded as an assumption, as a postulate, which satisfies certain familiar human needs.[8] Subjected to analysis this postulate turns out to be, in the rough, "an active assumption or acknowledgment of something more than the data of consciousness." The immediate data are of that fragmentary and transient nature which was earlier noted. Hence judgment must do more than reduce these present data to order; it must assert that context beyond them in which they exist and in which they have their real meaning and truth. This is, again, the corrected restatement of the Kantian problem. We are not faced with an incredible act of thought which forms sense-data as such, but with the act of thought which supplements the specific and empirical givens, in their temporal limitations, with the larger setting which gives them objectivity. This restatement at one stroke does away with the trans-empirical Ding-an-sich, putting in the place of a trans-empirical Reality, a trans-momentary one, and with the subjectivistic character of sense-data, in any sense of subjectivism which identifies them with a particular knowing self; – since sense-data are given in the most emphatic sense of given.

The sketch which Royce sets forth of the psychology of the process of the postulating activity of thought makes explicit the voluntarism implicit in the idea of the postulate. It is quite unnecessary to recall its details to you. The preface of the book makes an acknowledgment to Professor James, and the address of 1903 to which I referred at the outset expressly connects the

[6] *Journal of Speculative Philosophy*, Vol. XV, p. 371.

[7] The student of Royce will be interested in comparing this with the explicit doctrine of the Community in Royce's latest work. Peirce's influence is presumably effective in the earlier as well as the later writing, though it is less explicit in the *Religious Aspect*.

[8] *Religious Aspect*, p. 292.

influence of James with this voluntarism. The activity which transforms and transcends the immediate data is, psychologically, of the nature of attention; attention is essentially will, and it expresses interest.[9]

A voluntaristic element, persisting all through Royce's philosophy, is seen in his treatment of a cognitive idea. An idea to be cognitive must be a part of a judgment, or itself an implicit judgment. For a judgment to be true or untrue means that it agrees or does not agree with its object – an object external to the ideas connected in the judgment. Yet the judgment must always have something which indicates what one of the many objects of the world it picks out for its own, which one it cognitively refers to. In other words, the cognitive idea is, in its objective reference, an intent. The voluntaristic implications of the cognitive idea as intent are in no way elaborated in this document as they are, for example, in *The World and the Individual*, but the root idea is present.

It is no part of this paper to follow the logic of the treatment of the possibility of error and the method which leads to the conclusion: "All reality must be present to the Unity of the Infinite Thought" (p. 433). The purpose of the paper limits me to noting, first, that we have now found the ethical desideratum – the ontological reality of an organized harmony of all aims. For being a complete *thought*, a complete knower, it must have present in it all desires and purposes, and being a *complete* or perfect knower, it must also present in itself the realities in which aims find their realizations. Secondly, we note that in the formulations of this absolute knowing consciousness intellectualistic considerations predominate to a greater extent than in Mr. Royce's subsequent formulations. The Infinite Truth is conceived by predilection as Knower; it is referred to as Seer, as Spectator, as Judger. The function of Infinite Thought in *knowing* our aims and *knowing* the objects in which they are fulfilled is most dwelt upon. In the treatment of the problem of evil, however, that voluntaristic aspect of the Absolute which is made so explicit in later writings appears in germ. Goodness is not mere innocence but is transcending of evil. In the divine our evil is present but is transcended in good. But such transcendence is by way of conquest. The cognitive Seer possesses also a Universal Will realized in it.[10]

It is not my intention to engage in criticism of either the conclusion or the method followed in reaching it. I shall, however, indulge in a few comments which may suggest the direction which my criticism would take if occasion and time permitted. In the first place, I would point out that all solutions are relative because relevant to the problem from which they set out. In the last analysis, everything depends upon the way in which the problem is formed

[9] *Religious Aspect*, pp. 308–324.

[10] *Religious Aspect*, pp. 456–459.

and formulated. With Mr. Royce the problem is fixed by the results of the Kantian philosophy, taken in its broad sense. It seems axiomatic to him that the problem of knowledge is the problem of connection of sense-data which are facts of consciousness with the spontaneous constructive activity of thought or judging – itself a fact of consciousness.[11] It is significant that his discussion of the possibility of error sets out with a provisional acceptance of Ueberweg's definition of judgment as "Consciousness about the objective validity of a subjective *union of ideas*" (italics mine).

My second line of comment may be introduced by reference to the fact that I have spoken of the voluntarism of Royce, not of his pragmatism. I have done so in part because pragmatism (while it may be construed in terms of facts of consciousness, and so be identified with a psychological voluntarism) may be stated in non-psychical terms. But in greater part it is because the original statement of Royce, the one where a critical voluntarism still lords it over an ontological Absolutism, conceives will purely as Act. It is the *act* of Acknowledging which is emphasized. There is no reference to determination or measure by consequences. Now Peirce repudiated just such a position. He says, referring to Kant, that this type of position would be Practicalism, and that he adopted the word Pragmatism, still following a Kantian suggestion, to emphasize empirical consequences. The importance attached by James to consequences, last things, as a test of pragmatism, is well known.

Voluntarism rather than pragmatism is found in the Roycean notion of judgment. When intent or purpose is conceived of as the essence of judgment or cognitive idea, the intent is to know. The reference is intellectualistic; connection with the object intended is cognitive, not practical. As "attention constantly tends to make our consciousness more definite and less complex" (p. 316), so of the process of thought knowing, it is said: "The aim of the whole process is to reach as complete and united a conception of reality as is possible, a conception wherein the greatest fullness of data shall be combined with the greatest simplicity of conception" (p. 357). Construing the operation of fulfilling a supreme cognitive interest in terms of purpose and will is a very different thing from construing the cognitive interest in terms of a process of fulfilment of *other* interests, vital, social, ethical, esthetic, technological, etc.

Finally, just because consequences and the plurality of non-intellectual interests which cognition serves are ignored, the ethical voluntarism of the

[11] In the first published writing of Mr. Royce with which I happen to be familiar, entitled, "Schiller's Ethical Studies" in the *Journal of Speculative Philosophy*, Vol. XII, p. 385, the peculiarity of Kant is stated as follows: "Kant's philosophy is a glorification not of self but of Consciousness. In Consciousness is all knowledge rooted, through Consciousness is all truth known," etc.

essay of 1881 is itself an absolutism – ethical to be sure, but absolutism. The acknowledging activity must finally be justified by "the significance – *i.e.*, the moral worth – of this activity itself." It would be hard to find anything less congenial to the ethical side of pragmatism than a doctrine which justified moral purpose and motive by something residing in its own activity, instead of in the consequences which the activity succeeds in making out of original vital and social interests in their interaction with objects. Putting the matter somewhat more technically, the transition from the voluntarism of the early essay to the intellectual absolutism of the later book was indeed logically necessary. A will which is absolute is purely arbitrary, and its arbitrariness leads to scepticism and pessimism for the reasons pointed out by Royce. "Will" needs a rational measure of choice, of preference, in the selection and disposition of ends. If it does not find this measure in a coordinated foresight of the consequences which depends upon acting from a given intent, it must find it in some *pre-existing* Reality, which, of course, is something to be known. In short, what the transition from the voluntarism of the earlier essay to the intellectualism of the later exhibits, is not a change from pragmatism to absolutism but a recognition of the objective absolutism latent in any ethical absolutism. I would go as far as to suggest that the ulterior issue involved in the theory of knowledge is whether regulative principles have a prospective and eventual reference, or whether they depend upon something antecedently given as an object of certitude – be it fixed ready-made goods, fixed ready-made rules, or fixed Absolute.

THE EARLY PRAGMATISM OF JOSIAH ROYCE

George Dykhuizen. "The Early Pragmatism of Josiah Royce." *The Personalist* 18.2 (April 1937): 126–133.

In the years 1878 to 1881, when Royce was making his first contributions to philosophical literature, it was clear that he had definitely identified himself with the pragmatic movement, and had adopted James's theory of knowledge as his own. A scant four years later, however, in the year 1885, with the appearance of his first published book, *The Religious Aspect of Philosophy*, it was equally obvious that Royce had experienced a radical change in his point of view and had adopted a theory of knowledge based upon a form of absolute idealism. The steps in this transition and the reasons to be assigned for them constitute an interesting as well as important chapter in the story of Royce's philosophical development.

Royce was from the first impressed with the idea that the present moment alone is real and that everything beyond the immediate present is the product of postulate. In the year 1878, in his unpublished *Thought Diary*, he wrote:

> Every man lives in a Present, and contemplates a Past and Future. In this consists his whole life. The Future and Past are shadows both, the Present is the only real. Yet in the contemplation of the Shadows is the Real wholly occupied; and without the Shadows this Real has for us neither life nor value. No more universal fact of consciousness can be mentioned than this fact which therefore deserves a more honorable place in Philosophy than has been accorded to it.[1]

This idea that the data of the present alone are real and that when taken apart from a postulated past and future they are entirely meaningless serves as the point of departure for Royce's early epistemology.

[1] "Thought Diary," Berkeley, 1878–9, Harvard University Library, Unpublished, entry for April 3, 1878. Cf. also, "The Nature of Voluntary Progress," *Fugitive Essays*, p. 113; "Tests of Right and Wrong," *Ibid.*, p. 199 ff.; "On Purpose in Thought," *Ibid.*, p. 249 ff.; and "Kant's Relation to Modern Philosophic Progress," *Journal of Speculative Philosophy*, XV, 376 ff.

In the essay entitled "On Purpose in Thought"[2] (1880) Royce discusses the problem as to the final end of purely theoretical thought. Among the theories rejected is that which holds that the purpose of thought is to produce ideas which correspond to an external world. Royce's objection to this view are that we cannot understand how an idea can correspond to a reality which by hypothesis is alien to it and that we cannot understand how we are to get outside the narrow circle of our ideas to know whether or not the purpose of thought has been realized. The rejection of the theory of correspondence is mentioned because in the very next year it becomes the cornerstone of Royce's own theory. For the present, Royce maintains that the true purpose of thought is to build up "an ideal picture of a world of experience that shall be seen as One."[3]

Royce both agrees and disagrees with Kant as to the mechanism by means of which thought attains its end. Royce agrees with Kant that in consciousness there is always a *given*, which the mind passively receives, and also a spontaneous activity of thought. But Royce disagrees with Kant as to the nature of these two factors in the cognitive process. For Kant, thought rearranges its sense-material and makes it conform to the laws of the mind. For Royce, on the other hand, the *given* is ultimate. The present moment with its spatiality and temporal sequences is complete in itself and needs no "officious understanding" to rearrange it. What the mind does is to give to the sense-data of the "puny present moment" a reference to the past and future. It does not enter in and give form to sense, but, getting its cue from present sense, it constructs a world into the past and future.[4]

Our thinking activity occurs in order to enable us to satisfy certain needs of our nature, and receives its ultimate justification from its moral worth.[5] In *Fugitive Essays* Royce says:

> Beliefs are always the satisfaction of individual wants.... The adjective "true" is applied to a belief by the one who's intellectual want it satisfies, at the time when it satisfies them.... A system of beliefs is held, just as a system of government endures, so long as it seems to the men concerned advantageous to cling to it. [6]

Truth, however, is not a private individual affair. "My needs are narrow and changing. It is humanity in its highest development to which truth will be acceptable."[7] For one's personal narrow views should be substituted the broader social view of mankind at large.

The influence of William James on the thought of Royce at this time is clearly marked. In an article written a considerable number of years later Royce comments on this stage of his thinking and speaks of having been "deeply influenced by Professor James's earlier lectures and essays." He further says:

> I may venture to tell you that once in my life, before I fell a prey to that bondage of absolutism wherein now I languish, there was a time when I was not a constructive idealist of any sort, and when, if I understand the meaning of the central contention of pragmatism, I was meanwhile a very pure pragmatist.[8]

That Royce at this time was not entirely satisfied with James's theory of ideas is indicated in an article which appeared in the year 1882, the essay entitled "Mind and Reality."[9] In this article Royce discusses and accepts the idealism of Berkeley. In his discussion he gives a glimpse of one of the reasons why he found James's theory of ideas inadequate and why he inclined to Berkeley's theory of idealism. Though he remained convinced of the truth of James's doctrine that ideas are essentially practical in character, Royce was equally convinced that this doctrine did not state the whole truth about ideas. While true ideas do lead to successful activity, they have another characteristic which explains why they are successful, namely, they correspond to reality as it actually is. This reality is not the creation of any practical intention of ours, but is in some way independent of our ideas and stands authoritatively over against them. In contrast to his former position that thought does not aim to correspond with an external reality, Royce now asserts that the theoretical demands of our thought seem to require that there be an external reality that corresponds to our ideas and so gives them truth. Royce felt that James's doctrine was only a half-truth and needed to be supplemented, but not rejected. The philosophy which Royce thought offered the greatest promise for the correspondence theory of ideas was that of Berkeley which

[7] "Doubting and Working," *Fugitive Essays*, p. 338.

[8] "The Eternal and the Practical," *Philosophical Review*, XIII, p. 118.

[9] Cf. *Mind*, VII (1882), pp. 30–54. An article entitled "'Mind-stuff' and Reality" preceded the one mentioned. In it Royce had promised a later article which would be "just to the facts of consciousness and adequate to the demands of the philosophy of nature." (Cf. *Mind*, VI, 1881, pp. 365–377.) The essay on Berkeley is the one promised.

Royce now makes his own. "Our thought is true by reason of its correspondence to the facts of an actual consciousness external to our own."[10]

Though Royce expressly states in this article that his acceptance of Berkeley's philosophy is due to the theoretical demands of thought, it is fairly certain that the moral and religious demands of his nature also inclined him to that theory. In his earlier essays Royce had been maintaining that the essence of the religious attitude is "neither optimism nor pessimism, but simply earnestness, determination to make the world significant."[11] But such a view is really quite disheartening in the light of the little we know about reality. What hope and comfort can be derived from all our striving, he asks later, in referring to his early philosophy of religion, if we are always confronted with the disheartening thought that the next moment may be the last?[12] Berkeley's theory, since it postulates that the universal consciousness is a divine spirit, makes it possible for us to believe that "universal goodness is somehow at the heart of things."[13] And an adventurous faith in the existence of a universal goodness and its eventual triumph furnishes us at least with an incentive for continued striving.

The reasons for Royce's transition from Berkeley's theory of ideas to that of absolute idealism are of equal interest. And again it would seem that both practical and theoretical considerations are at work in Royce's mind. In the first place, Royce recognizes that he has escaped from the religious and theoretical skepticism of his earlier essays only by a sheer act of will. He has postulated the existence of a universal and good consciousness, but he has by no means proved its existence. And Royce holds that the ways of postulates, while superior to that of a resigned skepticism is by no means the ideal way. He writes:

> The world of postulates was a brighter one only because we determined to make it so. But there was something lonesome in the thought that the postulates got, as answer from the real world, only their own echo, and not always that. Their world was rather their own creation than an external something that gave them independent support.[14]

The way of postulates does not give us that which we so ardently desire, namely, an absolute assurance that all our moral striving shall not have been

[10] "Mind and Reality," *Ibid.*, p. 35.

in vain. "Courage indeed we must have, but is religion no more than courage? Nay; we must have if possible some eternal Truth, that is not our postulate, to rest upon."[15]

It was in his attempt to meet the theoretical weakness of Berkeley's theory of knowledge that Royce finds what he believes to be the "eternal Truth" which leads him out of a world whose existence can only be postulated and into a world whose reality he believes can be logically demonstrated. Though Royce has accepted Berkeley's epistemology, he has done so only provisionally, for he recognizes that Berkeley's theory is burdened with an inherent subjectivism which makes it impossible for him to give an adequate account of how we can know when our ideas are true. In the years immediately following the publication of the article on Berkeley, Royce devoted himself to a search for a way out of subjectivism and its attendant skepticism. The manner in which Royce stumbled upon the path which was to lead him out of his difficulty, he himself tells us:[16]

> From the depths of this imperfectly defined skepticism, which seemed to him provisionally the only view he could adopt, the author escaped only by asking the one question more: "If everything beyond the present is doubtful, then how can even that doubt be possible?" With this question that bare relativity of the present moment is given up. What are the conditions that make doubt logically intelligible? These conditions really transcend the present moment. Plainly doubt implies that the statement doubted may be false. So here we have at least one supposed general truth, namely, "All but the immediate content of the present moment's judgment, being doubtful, we may be in error about it." But *what then is an error?*

In answering this question Royce comes to his well-known conclusion that if the possibility of error is to be made intelligible we must hold to the existence of an all-inclusive and all-knowing mind whose thought constitutes "Absolute Truth and Absolute Knowledge."[17] For then an error can be explained as "an incomplete thought, that, to a higher thought, which includes it and its intended object, is known as having failed in the purpose that it more or less had, and that is fully realized in this higher thought."[18] Moreover, the subjectivism of Berkeley's theory is overcome, for,

[15] *Ibid.*, p. 332.

[16] *Ibid.*, p. 389–390 (Italics Royce's).

[17] *Ibid.*, p. 423.

[18] *Ibid.*, p. 425.

> You, in one sense, namely never *do* or can get beyond your own ideas, nor ought you to wish to do so, because in truth all those other minds that constitute your outer and real world are in essence one with your own self. This world of ideas is essentially *one* world, and so it is essentially the world of one self and *That art Thou*."[19]

In these early beginnings of Royce's epistemology there are discernible certain *motifs* which persist throughout his entire intellectual development. One such *motif* is the desire to harmonize the voluntaristic and intellectualistic interpretations of the nature of ideas. For in this early period as well as in all later periods of his thought Royce never discards the doctrine of James that a true idea is one which fulfils the purpose for which it was called forth. On the other hand, he cannot but feel that a true idea is one which also faithfully corresponds to an external object which stands authoritatively over against it. The problem of making consistent these two different theories of ideas is never frankly undertaken by Royce till he writes his *magnum opus*, and then the proffered solution becomes the cornerstone of his main argument.[20]

Another prominent *motif* in this early period is the religious one. In his early writings as well as in all the later ones Royce is deeply concerned with arriving at a theory of knowledge that will be not merely theoretically satisfactory, but one that will also furnish support to a religion of assurance and comfort rather than to one of courage and risk. It is this deep desire on the part of Royce which undoubtedly moves him to attempt to demonstrate the existence of an absolute and divine mind whose will is eternally triumphant and whose purposes are eternally fulfilled. How such triumph and fulfillment in eternity can be harmonized with struggle and defeat in time constitutes another crucial problem of Royce's philosophy.

[19] *The Spirit of Modern Philosophy*, p. 368 (Italics Royce's).

[20] Cf. *The World And the Individual*, Vol. 1, in which Royce discusses the internal and external meanings of ideas.

Section Three

Writings of John Elof Boodin

THE OUGHT AND REALITY

John Elof Boodin, "The Ought and Reality." *International Journal of Ethics* 17.4 (July 1907): 454–474.

Physical science attempts to describe reality in terms of three dimensions or independent variables, *viz.*: time, space, and energy. The philosophic meaning of these I have attempted to define elsewhere.[1] If we look a little more closely, however, we shall find that another dimension is implied besides those it avows, *viz.*: that the universe is amenable to ideals; that the flux of things has meaning. This tacit demand, which is the very spirit of science, cannot be reduced to mere monotonous uniformity; it has nothing to do with spatial distance; it is not accounted for by the mere transmutations of time, which must, on the contrary, be evaluated and given direction from another dimension.

True, materialism has always insisted that such a dimension is superfluous. But materialism makes far too great demands on our credulity: Reason grafted on chaos by accidental variation, ideals superimposed upon the chance play of atoms by accident, and this the truth, the absolute truth about it! Far saner seems to me the attitude expressed by Plato in the *Meno*: "That we shall be better and braver and less helpless if we think we ought to inquire, than we should have been if we indulged in the idle fancy that there was no use in knowing and no use in searching after what we know not; that is a theme upon which I am ready to fight, in word and deed, to the utmost of my power." For must not the materialistic assumption that truth is an accident prove suicidal to materialism itself? Materialism, too, is founded upon a faith in ideals. Democritus, no less than Plato, tries to penetrate beyond the mere seeming, though for the former the real truth is atoms and the void, for the latter, the idea of the good. We must somehow provide for value and significance in our world. Else why philosophize? If truth is an accident, if the flux of things has no absolute direction, then truth and error, virtue and vice are the same, and it becomes as absurd to speak of a materialistic philosophy as of any other kind. The same accident that makes ideals can unmake them. I cannot conceive of truth as even an ideal limit in such a world.

[1] See especially the author's monograph, "Time and Reality," No. 26 in the *Psychological Review* Monograph Series; also his articles on "Space and Reality" in the *Journal of Philosophy, Psychology and Scientific Methods*, Vol. III, Nos. 20 and 22.

To have truth and worth in the universe it is not necessary to be "stoppers of the universe," but it is necessary that the process should be in some way selective. As in the dark all cows are gray, so in a flux without direction there can be no valid distinction of values. I cannot agree with many venerable thinkers that only a static universe guarantees worth. On the contrary, I cannot see how ideals or worth can have any meaning in a static world. In such a world everything is, as it were, dumped together, and error and evil, in so far as they exist, have as much claim as truth and goodness. Ideals can only have meaning in a selective process. Even the ideal of uniformity can have meaning, as Poincaré has shown, only in a universe of flux. For it exists in the service of prediction, and what prediction could there be in a stillborn world? Flux on the one hand, and an absolute direction eliminating what is contrary to it on the other: that is all the guarantee we need.

This direction is not constituted by what each individual desires. To make the satisfaction of impulse its own criterion would destroy all criteria. For impulse is legion, and life would resolve itself into a chaos of conflicting desires; into what seems to each individual moment. If satisfaction is the test of worth, then whose satisfaction, that of the pig or the man, the fool or Socrates? The worst tragedy of all perhaps is that some are satisfied when they ought not to be. The optimism that the satisfaction of impulse is its own guarantee, presupposes a preëstablished harmony between inclination and right, the individual and the whole, the present and the future, which has not been attained and which can only come by the accommodation of impulse to a standard more objective than itself. The limit which in the end determines worth must itself be independent of impulse. It must determine survival. That definite lines of conduct exist must somehow be due to it. This is real idealism, as opposed to naturalism under whatever guise, idealistic or materialistic. Naturalism makes the Ought a mere function of what is. On the contrary, it must legislate to that which is. What pleases may not be what ought to please, and if we indulge in tendencies that ought not to please us, we do so at our own peril.

Santayana holds that the ideal must be the outgrowth and index of impulse; else there could be no false judgments. But how could there be either true or false judgments if impulse is its own criterion? These involve a reference to a constitution beyond impulse. I am quite ready to admit that ideals appear at a certain stage in the biological series; but when they appear they appear as leaps, not as mere products of the past. But why do such leaps rather than others have survival value? This must be because the universe somehow has a direction of its own. It is not accounted for by mere chance. If ideals cannot pass upon impulses unless they grow out of them, they surely cannot do so if they *merely* grow out of them. They must have their own credentials. Strange that thinkers who ridicule Plato for hypostatizing the Idea of the Good, which when properly understood is more than

an hypostasis, should find it so easy to hypostatize the mechanical ideal of atoms and molecules!

To say with the Hegelians that the ideal is already implicit or potential in the impulses must mean very much the same thing, if it means anything. That impulses are good or bad is hardly implied in the impulses. The question of worth can only arise when impulses are evaluated according to a context. That the impulsive satisfaction has worth in the end is not due to its being desired, but that it fits an objective constitution, present and future. This gives "immortal intent" to the process. That the eternally prudent may be sacrifice, that what it aims at cannot as such survive, can be no part of short-sighted impulse.

Hedonism when sorely pressed must have recourse to "on the whole and in the long run," not realizing that it thus abandons satisfaction or pleasure as the ultimate standard, and substitutes a selective constitution. It is this, and not the mere subjective satisfaction or dissatisfaction, which decides what structures can survive and therefore what pleasures can survive.

Neither does self-realization furnish a standard. Consistently stated, it is simply natural history, not ethics. Perhaps the most picturesque statement of this doctrine is the speech of Aristophanes in Plato's Symposium. The myth of the division of the double men and double women and the men-women and each half longing for the other, signifies that love, or the yearning of the soul, means self-completion or the attaining of one's own, the complement of one's being. But there are many types of selves, and each type desires its own fulfilment. If self-realization is to be the criterion of life, what self is to be realized, the baboon self, the pig self, or what sort of self? If all but human selves are to be excluded, what sort of human self? Not the criminal self nor the insane self, surely? Only a normal self could be the standard. As Plato says, It must be a very wise man who is to be the measure. But what is normal?

Psychologically viewed, the ego may sometimes aim to realize or define itself. It may aim to realize social institutions. It does aim to realize its own tendencies, egoistic and social. But what determines the worth of the activity is not the mere realization of tendencies, but its conformity to the ideals of the race and ultimately to the direction of history. Perhaps such a self has no business to be. Its whole universe or perspective may be sordid and mean, its complement brutal. In that case the ethical process is not self-realization, but the elimination of that type of ego. The doctrine of self-realization, tacitly at least, assumes a preëstablished harmony between the ideals of the individual and the whole, or that if each one desires his own realization he at the same time desires the good of the whole. Such a fallacy could only be maintained by such ambiguous shiftings as that between the real good as opposed to the apparent, the true to the actual, the eternal to the temporal, in all of which it takes no great insight to see that there is a reference to a constitution beyond the individual ego.

Even biologically, self-realization can hardly be seriously maintained. We have become so constituted as a result of the demands of the universe upon us that we respond in certain ways. To look out for ourselves is only one of the many demands that are made upon us. Our adjustment in the nature of things is largely institutional and must become more so as a result both of biological and social heredity. To fit into institutions, present and future, must, therefore, be the biological test of an ego worth preserving. The test in the end is extra-individual. And as institutions too are subject to the law of survival, the test becomes extra-institutional as well. It again implies the attribute of absolute direction. A man, moreover, who should be as self-conscious as the self-realization theory demands would be a pretty sickly and clammy sort of specimen. Not of self-completion but the yearning for the Good, to refer to Plato's Symposium again, is true realization.

Since Spencer's time it has been fashionable to speak of ideal activity as adjustment. It is not always clear what the adjustment is to. It must be to some sort of environment. But what is the environment to which the soul must adjust itself? It is not merely present sense-perception surely. The adjustment must be to the future as well as to the present, *i.e.*, the present ideal attitudes must fit into the future process of life. To hold that the ideal is at each stage of the process a mere function of the *is*, the result of the accidental shooting together of the various tendencies of human nature, and also hold that it controls these tendencies, is even more incredible than the materialistic statement that the ideal is a mere epiphenomenon, irrelevant to the going on of the real process. But the latter bankrupts all truth-seeking and all ideal endeavor. Epiphenomenon is after all only a technical name for a lie. Why should the mechanical process produce something which does not express its real nature, has nothing to do with its existence, an unaccountable illusion?

The most important part of the adjustment of civilized man is to the institutional ideals of the race. These furnish a provisional measuring rod for individual life. But social agreement, while on the whole a safer test than individual desire, is not absolute. Can any thinking man be satisfied in merely obeying the oracle of Delphi, "to worship the gods according to the laws of the land"? Socrates may have meant to do so, but the Athenians were right, that he introduced strange gods, new ideals hostile to their conventions. Every institutional embodiment of the Ought is relative.

Neither can reason furnish an absolute criterion. Sometimes, indeed, the individual is wiser than society. Else there could be no progress. As Heraclitus says: "It is the law, too, that we obey the counsel of one." But individual reason at best is dependent upon its historic setting. It is limited by the axioms of the past, the ideals and sentiments of the age. It very easily finds arguments for the stake or the golden rule, the Inquisition or the French Revolution, according to its setting. An appeal to pure reason cannot lift us above the relativity of history.

Even if there is a more comprehensive reason than human reason; granting that such a reason can know the total object of science, the present constitution of things, with its laws and uniformities, in a real time world such as ours, even such a reason could not read off the future. Its attitudes toward the future would still be postulates; and nothing would seem more certain than the transformation of present meaning. Even such a reason would presuppose direction, beside present omniscience for the validity of its judgments. Its judgments would have to fit into the future as well as the present to be absolutely true. How much more evident must it be that *our* reason does not constitute its own world, present and future! We cannot now be said to mean what we do not mean; and when a richer meaning supplants the poorer and more selfish, that is not because we meant more than we meant or because we wanted failure when we sought success. Paradoxes do not explain. Something must really have happened. And in the Ought process the superficiality of our former insights has come to light. If we learn modesty in regard to truth as we have it, that is not because we know more than we know or possess an absolute truth, but because we have learned from the past that our truth, however satisfying for the time, is provisional. There is a constitution which transcends our purposes whether individual or social. This selects or eliminates in the course of the process.

Our demands and postulates that there ought to be meaning and worth – demands which antedate our scientific constructions and our practical and aesthetic purposes – these are not simply the result of experience, because experience only comes to have meaning and value with reference to them. Provisionally we may regard them as biological categories. They do appear in the evolutionary process. They are involved in race experience and have been forced upon us by race survival. But this only pushes the question back. Why are they conditions of race survival? For we must look at these conditions not only from the point of view of the individual, but of the whole process. They must somehow be involved in the constitution of reality throughout the time process, thus to condition reflection and life alike. They are the manifestations or incarnations in history of the eternal Ought, which is with us always from nebula to society, for even the astronomer and the geologist insist that their facts must have meaning.

Evolution itself must derive its meaning from such a conception of absolute direction. Even such fragmentary cumulation of significance as we find would otherwise be meaningless, for we could have no reason for supposing that the later is any better or truer than the earlier, even on the whole and in the long run, or that the process ought to be read one way rather than the other, unless we assume such a direction. This is the real measure of the process. As regards the pre-rational stages of the process, whether individual or racial, cosmic or human, these would be irrelevant to reason unless they somehow prefigured or were prophetic of reason. That there shall be reason cannot be

an accident, if we can reason about things. When at last man awakes from the long slumber of the ages, pregnant with tendencies which ages of selection have forced upon him independently of his individual will, "he lays his hand on his bosom and feels it is warm with a flame out of heaven" – a yearning for that which is not and yet gives meaning and value to that which is. It is this which makes the time process ever mean more than it knows – not *its* wisdom, but rather that in spite of its blindness it comes to fit into a larger pattern. This makes the present, in so far as it is meaningful, fulfil the past in so far as it was meaningful; and as the checkered woof of the time process emerges out of its instinctive darkness into the future, it furnishes the warp which insures a continuous whole.

This Ought or direction cannot be a product. Reflection cannot create this Ought, this demand for meaning and unity, for it presupposes this very demand. Neither can time create it, for time has no direction, knows no ideal. It can but transmute endlessly that which is, each after its kind. What shall survive, if anything but chaos, must be left to another principle. For "time," as Heraclitus has so strikingly put it, "is a child playing draughts." In the flux of process, individual desire and social institutions, intuition and reflection, prove alike relative. What remains is only the direction. This must be absolute, else there is no meaning. This is the absolute ontological limit of truth and worth, forced upon the individual by the constitution of reality and the necessities of life, not a mere ideal positing.

Without an absolute direction I do not see how validity is possible. Any theory of the universe which distinguishes degrees of truth and worth, which holds that one state of consciousness may be better or truer than another, such a theory implicitly refers to a standard, a measure more comprehensive than each individual's momentary feeling or view point. To deny this is to land in skepticism with the contradictory implication of a standard more absolute than all, unless indeed we carry out our skepticism to the extent of denying the validity of our skepticism and so commit suicide. We may lay it down then that all evaluation, skeptical or believing, implies a standard transcending the immediate moment and valid for all. But the question remains: How must we conceive this standard? I see only two possibilities: We must either assume with the absolute idealist a complete, all-comprehensive, eternal consciousness, or an absolute direction. Of the former we must even now be sharers or possessors. We must move according to its logical necessity; we must unravel its logical categories; in the consciousness of its completeness we realize our finite fragmentariness. This hypothesis has been more fully discussed elsewhere. Suffice it here to say that if the universe is thus complete and perfect, it is difficult to see how this consciousness of fragmentariness or finitude should ever arise. Moreover, as the necessities of our existence call for adjustment to a world in which change and plurality with all their darkness play an

important part, it is difficult to see of what use such a perspicuous hypothesis can be.

If we take the universe, on the other hand, at its face value and acknowledge it for what it is – a stream of processes – then we must seek for another standard. As this standard cannot be comprehended within experience, individual or social; as it cannot be regarded as an accidental product of the process and yet cannot be merely external to the process, we must seek it in the direction of the process. If the process has an absolute direction dictating, not what can arise, but what can survive within the process, then the significance of the process as a whole, reflective or non-reflective, is guaranteed. And while we cannot read off an absolute truth when we do not have it, we have in this a limit, which however much it transcends our finite moments, yet furnishes the possibility of evaluating our finite degrees of truth and worth. The limit as posited by us partakes, indeed, of the finitude of our positing, but the conception of this limit, however it may vary with human experience, becomes effective none the less for our comparison. And on the absolute reality of the limit must depend in the end all validity, however relative, of truth and worth.

It is evident, therefore, that the concept of validity has a real basis only in a world which has absolute direction. If the process of the universe is merely a chance affair, no ideals can be enforced or be binding, whether mechanical or ethical. Science in such a world would have no guarantee for its ideals of simplicity and unity any more than ethics for its ideals of worth. What keeps warm the passion of science for these ideals is that in spite of the complexity of the world, growing ever more apparent in the course of new discoveries, the facts can be more and more sorted under common principles; the Chinese puzzle of a world does seem to indicate that some parts belong together, and the faith in spite of failure ever springs up afresh in the truth seeker's breast that the rest will yield to the same ideals.

Whether the time process has always been conscious of direction is not the question. This, while genetically interesting, has nothing to do with the reality of direction. We have not always been conscious of space and time and other characteristics of reality, but they have none the less conditioned behavior until we acquired the tools for recognizing them. So direction must have operated before the consciousness of it, to give significance to process when we come to reflect; and for that matter to bring about reflection. For why should we raise the question? The problem is, can we express direction or meaning as mere chance or happening on the one hand, or mere habit or uniformity on the other? It seems to me to involve another dimension besides these. Even a mechanical ideal implies the faith in meaning. If there was a time when reality was conscious of no meaning, it must at least have had a definite direction toward reason. The process must shoot into reflection by a law or tendency which reflection in retrospect can see to be inherent in the nature

of the process, and not as a result of mere chance. Otherwise reason loses all validity as well as efficacy, and the mechanical ideal becomes merged with the rest in the general chaos.

If it is the limit of an absolute direction that gives meaning to our finite and fleeting oughts, our relative ideals, must not the limit, then, be as real as the terms it limits? If we take the straight line and the varying curvatures of which it is the limit, the straight line is surely as real as the curves. I am speaking here of reality, not of worth. The straight line and the circle are worth more or are more significant than the multitudinous curves, but that is not the question here. If we grant the reality of our finite purposes, must we not grant also the reality of the limit which conditions their significance, which prevents their being swamped in absolute relativity or brute chance? Must not direction, without which process is unintelligible, be as real as the process? If it is helpful, moreover, to suppose that there is somehow in the universe such an ideal limit which regulates worth and survival; if even the nebula and biological evolution seem to involve such a direction to be intelligible; if when it becomes conscious of itself in man, it can control, and make significant, facts and impulses; if truth itself is more than an accident and we are not deceived that there can be approximation toward a whole of truth, goodness and beauty, then this limit cannot be merely our fiction, but must be involved in the constitution of the process.

I cannot see how the pragmatic movement, led by the brilliant James, can get along with less than this concept of absolute direction. If it believes that process is amenable to purposes and can be guided by purposes, that the test of ideals is their workableness, it must somehow account for the presence and place of purpose in the process. That the process is through and through reflective is a violation of the pragmatic principle itself, for there are surely some facts which we need not and cannot recognize as purposive. We seem, therefore, to be in a dilemma: Either we must accept materialism, that ideals are accidents and have no efficacy in the process; or we must hold with absolute idealism that there is no process, but that the universe is one complete whole, the purpose eternally fulfilled. In the former case truth becomes merely an illusion. In the latter, truth becomes inaccessible and the world as we have it is illusion. The only way we can steer safely between the Scylla of materialism and the Charybdis of static idealism is by keeping before our minds the concept of absolute direction. This makes purposive significance possible without stopping the universe. It also pieces out the ideal beyond our finite purposes instead of making it a mere unaccountable fragment in the process without any setting in the universe as a whole.

The perennial problem of the one and the many finds its only intelligible solution in the assumption of such an absolute direction. The dialetic whether the universe is really one, and the many an illusion – or whether it is really many, and the unity an illusion – has been waged long, though with bloodless

damage to both sides. The atomists of all types, whether believers in the quantitative entities of Democritus or the spiritual monads of Leibnitz or the qualities of Herbart, have found it necessary to account for the apparent continuity and unity as arbitrary and seeming. The monists again, from Parmenides down, have been equally forced to sacrifice the apparent plurality within the world. Brave souls who have had more respect for the facts than for logical consistency have compromised and admitted both the one and the many with varying emphasis according to their peculiar bias. One thing is certain, that on the basis of a static conception of the world, the problem of the one and the many remains as impossible as ever.

Nor is a dynamic conception of the world by itself any more satisfactory. That the universe is process or transformation does not tell us anything about its relative unity or plurality. Process in itself may mean greater chaos as well as greater unity. It furnishes no guarantee one way or the other. It tells us nothing in so far as it is a mere time process about its *whither*. And still we insist that our world shall be a whole and not a mere chaos. This is the eternal inspiration of scientific research as well as of practical life. Yet how ridiculously meager is the evidence for our faith. Kleinpeter tells us that his master, Mach, proceeds inductively as regards this unity, while philosophy proceeds deductively. That is amusing! Have the fair maiden's dreams of love, and her golden hair flying in the breeze, and the Kansas prairie dust-storm all been comprehended within one inductive unity? That they ever will be so is an audacious dream.

We are agreeing now that if there is to be any unity it must be a teleological unity. The dust-storm can only be understood as one with love's fair dream when they can be seen as part of one purpose. Plato felt his way toward such a teleological unity when he crowned his hierarchy of Ideas with the Idea of the Good. But the dynamic cement of process was lacking, and the loose stones would not hold together. If we assume the attribute of an absolute direction, it seems to me we shall have the necessary regulative principle. Granting on the one hand a universe of flux with ever new variations, and on the other an absolute direction, selective or legislative to this flux, in eliminating those transmutions which do not fit its direction – granting this not only as an experiential but as a cosmic principle, and a degree of unity at any one time would be guaranteed and in the long run the successive stages of the process would show cumulative significance, with a backward and a forward reference. Such a universe, too, with its original diversity of stuff to be transformed, with the possibility of ever fresh variations, not precluded by such uniformity as exists in the transmutions – such a universe would also account for the outstanding plurality and opaqueness in any given stage of the process. And as the process, moreover, is as eternal as the direction, the pluralism could not disappear, though perhaps it might grow more articulate and so make disjunctive judgments of the future more possible.

The conception of immortality again can be given real meaning only if we assume the attribute of absolute direction. Mere existence and the tendency to persist *in esse suo* cannot guarantee immortality. The question is not, does an individual desire to persist? Or does he have a specific content? But is he worthy to persist? Is the content significant? In the history of art and institutions, as well as in the history of thought, we learn that only those structures and contents which fit into the future of the process can survive. But if worth is to be a condition of survival, the process must be fundamentally and absolutely selective. It must have absolute direction.

Powerless indeed is this Ought to create its special content It cannot work *in vacuo*. The grist which it shall grind must be furnished by process. This is the result of free acts of willing subjects; or, lower down, of chance variations, the inwardness of which we are ignorant. Nor can the Ought arrest the flux, nor annihilate its space conditions; but within this process it can determine that what shall survive must have worth, the particular richness or coloring of it being due to the process out of which the Ought selects. The universe indeed becomes other for our earnestness or frivolity, our strenuousness or laziness. But this, at least, is true: that what survives must be in line with the direction of the process. The tragedy, moreover, lies not only in willfully missing the good, but in intending the good, and because of ignorance of the complexity of life and of the future, doing the evil; and the well-meaning man having to proclaim in the tragedy he has wrought: "Das ist nicht was ich meinte."

With reference to the stuff aspect of reality, the finite structure, with its content and uniformities, its impulses and meanings, at any one time, the Ought is non-being, *i.e.*, it is not stuff. And yet it can be no less real than being, for it determines its meaning and survival. It cannot work independently of the finite, but in the transmutions of that which is, it asserts its supremacy, for nothing can have meaning, and nothing in the end can be, without it. It determines the survival of stuff and ideals, which, for the time being, belong to the stuff side of things. For our ideals are structures striving to reflect or embody eternally the infinite direction. But their eternity is only intended; it is not real.

The Ought is eternal. Since the Ought is not stuff, mind stuff or any other stuff, it is not subject to time and process. Only stuff is transmutable. Having no content, not being itself stuff, for it determines the survival of the stuff-transmutations, the Ought itself is not subject to transformation. It remains eternal in the flux.

With Heraclitus I would agree that this direction is "the divine which feels all human laws." It is "the common" in the sense that it is valid for all and binding upon all, as opposed to the many who live "as if they had a wisdom of their own." Yet it is not the common in the sense of the identical, either in the many opinions or in the historic process. What is common to the savage

and the civilized man, to the fool and the wise man, would be pretty thin and meaningless. On the contrary, it manifests itself in the concrete process of history, in the real flux which is not merely a rearranging of bits of substance or mathematical models, as the atomists would have it. It is no doubt true that the common, *i.e.*, the institutional heritage of the race is, on the whole, the safest guide of life. Institutionality is the result of workability for the time being. But if the direction were merely the common, history would be a mere dead level without movement or progress. Its flashes of light must come first of all to the individual.

It is the / *δοω*, the path, of process and survival; but not the path in the sense Heraclitus meant it – an upward and downward path, from fire down to water and earth and up again, "fixed measures" being exchanged, a merely circular process in which nothing really happens. Not so with the real time process, where all uniformity or stuff is relative and permanency is merely an ideal limit. In the Protean guises of this process the Ought asserts itself ever and anon. And while it cannot stop the process, it determines what can have meaning and existence in the process. It is not the projection of the ideals of the individual or of the race at any time. Nor do they intentionally point to it. They point to their own realization except as they qualify themselves: Not my will, but the eternal Ought be done; and in so far they are contentless. The pointing or direction lies in the destiny "which shapes our ends, rough-hew them how we will," not fatalistically, but by eliminating those free acts or accidental variations which do not fit its direction. The Ought, like the voice of Socrates, only speaks in the negative. Its content is ever changing and ever new; or rather, it has no content: and yet though non-being, it determines the survival and meaning of that which is. It is the direction of history: and yet for us it is ever born afresh out of the process it determines. It has no concrete being except as it is thus embodied in the fleeting moments. It thus furnishes the direction in the trackless void of the future as it is continually incarnated into the finite. It thus throws the searchlight of truth ahead; and yet at every moment it is a new, because finite, searchlight, with a new color and radiance, always, however, determined by the same Ought.

The Ought is creative, but it creates not by production but by elimination. It is creative as the artist is creative, *i.e.*, by selection. It is superior to "essence," *i.e.*, to truth and beauty, for example, as historic products, because it determines their worth and survival. It gives beauty to the perishing things of earth. It is both the "heavenly pattern" and the artist. It is a real or ontological factor of the world, as Plato held. What Plato failed to see is that the Good can only create in a flux world and has no other content but the flux. Moreover it cannot be an Idea, because then it would be an essence and relative to itself. No wonder Plato feels dazzled and confused. It is transcendent and infinite. We can only grasp it as a limit. But as such it conditions all our thinking and conduct. It is not, moreover, a mere abstraction. It operates in the concrete

world of process. Only thus could it give significance to process. If Plato could only have made use of the conception of struggle and evolution (already dimly outlined by Heraclitus), then the world of flux and the Idea of the Good, could both have been accorded their due reality. He would not have had to confess failure as he does in the Parmenides.

If we cannot give any definite content to the conception of absolute direction; if it remains for us merely the demand for law and worth; if, to use Plato's metaphor, we cannot look upon the sun itself, what is its child, its phenomenal manifestation? What evidence for its existence in the finite, structural world do we have? As we have developed the feeling of extensity with complex instinctive coördinations to meet the reality of space; as we have developed the sense of duration with complex structural adjustments for measuring the flight of time process; as we have developed the feeling of effort to symbolize energy, so we have developed the feeling of Ought, with its tendencies and sentiments, and its sanctions in social institutions, to meet the demands of this fourth attribute of direction. That in the nature of things, just because the process is infinite and our ideals are part of the process, our ideals must be finite, does not invalidate the evidence of the *feeling for ideals* so important for the race. That, moreover, these sentiments and ideals are growing more essential and more adequate to meet the requirements of life must strengthen the faith in their efficacy and objectivity.

It is, indeed, as Kant maintained, the categorical imperative. It commands unconditionally. It does not grow out of our inclinations and impulses, but it determines the worth of these. Its sublimity surpasses the starry heavens, for the whole cosmic process is subject to it. In its consciousness we are mighty and free. We are part of another world to which the stuff world is subject. It is not the good will, but it determines whether wills are good or not. But just because it is an absolute limit; because all our finite ideals are relative to it; because it is the *rationale* of history and not its product, therefore no specific content can be given to it. The maxim of universality and all other maxims are but relative to it. We can only characterize it in the most general terms, and those, too, are finite. It means orderliness and comprehensiveness in the regulation of individual as well as social life. In Professor Palmer's apt phrase, "It is the law that there shall be law."

Perhaps that is the safest determination we can give, in terms of reason, of that which transcends and determines reason. Its concrete content must come in every age from its finite setting in human institutional life and in the individual soul. Thus we are able to meet our concrete duties in our generation.

The ideal must become concrete, as Kant saw, by being realized in a kingdom of ends. This is not so simple as Kant thought. For Kant every individual is a little god or absolute, legislating for all men and the universe at large. But on the one hand the individual historic will is not autonomous,

it must accommodate itself to the institutional life of the race; and the two may clash. Human beings, even when they think themselves most rational, do not legislate in the same way, and life must proceed by compromises. On the other hand, the institutional heritage is not final. The individual may be wiser than the institution. But both are subject to the eternal Ought; this alone is an absolute categorical imperative.

Like the First Mover of Aristotle, the Ought does nothing. It only remains itself. It does not itself move. It is not the cause of movement, however, but it determines by its existence the direction and worth of the historic process, and thus accounts for progress. Unlike Aristotle's God, too, it is not only transcendent but ever incarnated afresh into the finite, *i.e.*, it is the meaning we discover in the finite, but more besides. Else the finite would have no significance. Only thus could the yearning in the finite for the complete and whole originate. In being thus incarnated ever anew into human lives and the order of history, it can say with the Christ, "Lo, I am with you always, even unto the end of the world." It is the Spirit of Truth which guides and shall guide us in all truth.

This conception agrees with the Thomistic as against the Scotist position, *viz.*: that God himself is determined by the norms of goodness and truth, *i.e.*, by the Ought, rather than that these norms are the arbitrary result of God's willing. God on this theory would become the concrete, finite and individual embodiment of the Ought. In this lies his power as well as his goodness. But more of that elsewhere.

With Hegel I would agree that history has cumulative meaning. This holds, however, in the long run, and not always in the sense of logical continuity. History is a real process, not merely a system of logic, a scaffolding of categories. It cannot, therefore, simply be read off by logical implication. History is real happening with real tragedy and real success. It might have a different content and thus must be studied empirically. What the Ought determines is that what survives must have worth.

With Fichte I would agree that the universe has a transcendental constitution. But this constitution is not merely a transcendental system of knowledge, a *Wissenschaftslehre*, not even Fichte's, which he thinks our free wills reject to their own damnation. The universe is not so much an ethical system as an ethical process. That which is "over-individual," to use Münsterberg's picturesque term, is the direction of this process; and we are not merely view points within a system, but real actors determining the content and so the character of the world. It makes a difference how we will or fail to will to what the ethical process can realize.

The ethical process cannot be like the Buddhist Karma, for if life is simply the causal result of what precedes, there can be no attainment of an ideal; there can be neither good nor bad, but simply the automatic record of the cumulative result. Life must remain imprisoned in the iron grasp of the past.

No, causality itself must be relative. There must be some fluency in the process. But most of all, the criterion must not be simply a product of the past, but an independent variable in order that it may pass upon causality and flux alike. The Karma permits of no salvation; no waking up from the evil nightmare. The horrible dream must go on.

The faith in an absolute direction furnishes a sufficient guarantee for our ideal striving. This is not a mere Utopian or *laissez faire* optimism. There is real evil in the world, real maladjustments, false view points. But though the wicked flourish like a green bay tree, their type shall not prevail. The servant of Jehovah shall eventually triumph, though perhaps through labor and suffering. The righteous remnant shall survive and inherit the kingdom. Only the just state can maintain itself. And because the mills of the gods grind exceeding fine, though perhaps slowly, we can afford to be tolerant and to wait. "Let the tares grow with the wheat until the harvest." And the harvest is the sifting of the progressive process itself. In view of our ignorance of the future, our motto, just as far as decent living together permits, should be: Judge not. Let it be. The divine direction of history will see to it, in the struggle of ideals, that the superficial and ephemeral are eliminated. Thus man can labor and wait with confidence as regards the final outcome. And if he is made of the right kind of stuff he will be willing to have his ideals, yea, even himself, eliminated if unworthy to survive. In this willingness, at least, he will prove his superiority to chance.

Will the kingdom not of this world and the kingdom of this world ever be one; will stuff and Ought, the traveler and the path, ever blend into one unity? Will the third kingdom, prophesied by Ibsen in his "Emperor and Galilean," the kingdom of God-Caesar or Caesar-God, ever come? Not while the world is process. So long as there are transformations, so long must the mills of the gods grind, and so long will the content and meaning of the world be ever new. No, to make circumstance plastic in the service of the Ought is the task and the joy, too, of life, at least of healthy life. The real other, the completer life, is not an absolute system of truth which we now possess and intentionally hide for the purposes of the game, as the most illuminating present advocate of absolute idealism, Professor Royce, seems to hold; but the yet unborn, the insight we have not seen. Any theory which ignores this must make history and duty a mere farce. The universe is process, but through the process the Ought sets the conditions of survival and meaning.

There will always be tired souls, who want rest above all other things; but this must be a rest which the world cannot give, a rest in seeking and realizing the ideal. The satisfaction we *now* seek may itself in a further stage of the process be seen to be relative and unworthy. To stop at that would be lazy, cowardly and immoral. The real satisfaction lies ever beyond in the Ought. Art tries to steal from the fleeting moments of life their meaning or significance and frame it, and it rests us for a moment. But this satisfaction, too, is

relative. The songs of our childhood satisfy our soul no more. The satisfaction of the Greek world is not our satisfaction.

The only way, finally, which I can serve the eternal Ought is by serving for the time being the Ought incarnated in my meaning and in human history. To quote Heraclitus again, "It is not meet to act and speak like men asleep." Whether we are awake or asleep, whether we think or dream away life, we are subject to the law of change, and the law of direction. But if we think, we may enter into the eternal in some degree by striving to understand the direction of things and guiding our lives accordingly; we may become creators instead of mere bubbles on the stream. By acting out my best purposes, by living my highest insight, there shall come, perhaps through failure, perhaps through partial success, how, I do not know, new insight, new capacity for work, love, and appreciation. The eternal Ought will see to it, if we are sincere, that we do not permanently miss the path in the trackless unknown. But our illumination must be the Ought as now incarnated in human history. The next incarnation will come in the fullness of time. The voice out of the dark is enough for the next step.

THE POSTULATES OF TRUTH

John Elof Boodin. "The Postulates of Truth." *Truth and Reality: An Introduction to the Theory of Knowledge* (New York: Macmillan, 1911), chap. 7, pp. 123–145.

The pragmatic movement has emphasized practically altogether the *function* of truth in relation to life as a whole. The function of truth is to regulate conduct; and truth, therefore, is valid when it flows into its anticipated consequences. These consequences are further experiences. Epistemologically truth rests on experience; and experience, as one moment of individual consciousness, rests on more experience, the present moment becoming confluent with the new moments in the ever expanding restless stream. The flow of this stream has its direction determined by the past and present tendencies, but it also has its own individuality, as the old elements flow into the new situations, whether chemical or psychological.

What should be made clear, however, is that pragmatism is a theory of the function of truth, and does not deal with the whole problem. By emphasizing this we may be able to attract attention to the far larger and more complicated problem of the form of truth. To be sure, even in dealing with the problem of function, pragmatism has been inclined to limit itself to the biological function of truth – truth as a factor in the adjustment to the perceptual environment, or a tool for dealing with perceptual situations. Pragmatism has been inclined to neglect the sporting interest in truth – truth as setting its own problems, choosing its own constitution, and thus elaborating its logical consequences to harmonize with its posited world. But this, while it alters our conception of the scope of truth, does not fundamentally alter our conception of its function, which still remains to regulate conduct – the conduct of the understanding as well as the adaptation to a perceptual environment.

But granting that thought comes to light in the stress and strain of experience – whether forced upon us by the environment or posited as the logical play-ground of the will – there remains the problem of the nature of thought itself. Is the form of thought originated by the practical situation – the consciousness of difficulty or disorganization out of which it arises? In the case of generating electricity by friction, say by two sticks of wood, we are setting free a preëxistent energy, the nature of which we must respect; and the friction simply furnishes a condition for its manifestation. Is it so with thought? Or is thought created outright by doubt? Does it really grow out of

the infra-logical antecedents? In that case, is the form, too – the laws of thought – created? Are they set by the will as its temporal conventions, or must they be acknowledged by the will as eternal? In the former case, are they just what the *individual* posits them as being, or are they universal? But, if without conventional agreement we find ourselves acknowledging these laws whenever we think, they would seem to be independent of the will and have a preexistent character. In Plato's terminology, they would seem to be "recollected" rather than created in our coming to consciousness of them. The laws of thought would seem to be *discovered* through their use in experience, rather than *made*.

If we look forward to the end of thought, instead of backward to its origin, is thought simply a tool to an alogical end? Or does thought enter into the end of life as an intrinsic factor – not as a scaffolding merely for a higher stage of mystic immediacy or biological activity, but as the law of the process of life? What relation does thought, with its postulate, bear to life as a whole? Such, and many other questions, still remain, after we have agreed upon the regulative function of thought in experience. To ignore the structural aspect of thought means a very invertebrate theory of knowledge.

One thing is certain, that the teleological value of thought cannot be understood apart from its correctness, its technique. The syllogism, with its rules, is a valuable machine for abstracting and investigating valid thought relations, in spite of the contumely heaped upon it. What is true of the syllogism, as a device for ascertaining formal relations, is true likewise of the so-called inductive canons for ascertaining causal relations amongst facts. The practicality of our thinking about perceptual situations lies in its being correct thinking, and Mill's canons are an important device for such procedure. If it is true that the procedure explains the value of the device, it is also true that the procedure is made possible by its being a correct device.

Are these rules arbitrary? The rules of athletics are not arbitrary, though they may seem so to the spectator. They are the result of studying the laws governing both the constitution of the players and the appreciation of the spectators, so as to produce, on the whole, the best result for player and spectator alike. The conditions governing the game may be said to preëxist in human nature and to be binding if you choose to play the game and to play it effectively. So with the laws of thought. The question, then, arises: What are those laws of thought which in all our reflective procedure we must respect? And what is the basis of their authority? To begin with the first question: What postulates are implied in all thinking and condition its procedure?

I shall try to show that there are four presuppositions or laws which are implied in all our knowing, viz.: the law of consistency; the law of totality; the subject-object form, or the law that knowledge must be representative; and the law of finitude. The use of these terms will become clear, I trust, in the discussion.

1. The Law of Consistency

First of all it will be generally agreed that we presuppose consistency. Under the law of consistency I include what are usually termed two laws – the law of identity and the law of contradiction. It requires no proof to show that these are merely different emphases of the same meaning. If we use the old formula, *A* is *A*, to symbolize the so-called law of identity, the law of contradiction simply brings out the implication that if *A* must be taken as *A*, if black must be taken as black and Socrates as Socrates, throughout the logical procedure, *A* cannot also be taken in the same sense as not-*A*. This is true, but it is an implication rather than an independent law. Fortunately, the concept of consistency comprises both of these implications, viz.: that for purposes of thought we must be able to take *A* as *A*, and that if we must thus take it, we cannot take it as not-*A*.

But the term consistency has a further advantage. It not only comprehends both of the old formulas, but it also brings out what they failed to do, namely, that it is identity within a variety of individuals and changes with which we are concerned. Truth would be meaningless within an abstract world in which *A* is bare *A*. It is the constancy of *A*, as making possible description and prediction, that makes truth mean something. The law of consistency means that in the variety of experienced facts and changes, there must be a certain constancy of content, if we are to make any predicates about our world. Unless we can take our abstract meanings, qualities, relations, or whatever we may be actively interested in, as the same, in spite of flux, we can make no judgments or inferences. This means, formally expressed, that we must take *A* as *A* throughout our logical procedure, and that we cannot take *A* as not-*A*, if we would reason about the meanings or things of our experience. This implies that, for logical purposes at least, there are such recognizable identities as furnish leadings or threads to the plurality and flux of experience.

Identity in the variety of situations, empirical or formal, must always be taken as identity for a purpose, in order to be concerned with truth. Mere repetition *per se* would have no significance for truth. Animals, too, have to adjust themselves to a world of uniformities; and they develop instincts and habits, but no truth. It must be identity as leading to identification; and this means that the situations may, in other respects, be quite diverse. In fact, here lies the significance of the identification – in taking the somehow different as identical for the purpose. 4 = 2 + 2 for the purpose. The Jones of to-day, however outwardly changed from the Jones of your school-days, is still the same in fundamental characteristics, and merits the same loyalty and friendship.

We can see that nominalism, in the bald sense of absolute disparateness, would make truth impossible. In such a world there could be no concepts and no inference, as each particular content must be taken as unique. Nor is it

necessary to go to the opposite extreme, and speak of universals or identities as existing prior to the instances, and these as differentiations of this identity, as even Bosanquet does. This makes knowledge quite as impossible as does pure nominalism, for it is absurd to suppose that from identity any instances could be differentiated. It is enough for truth that certain characteristics can be taken as the same in various individuals or groups, and that this makes it possible to say something about the conduct of these individuals or groups so far as these characteristics are concerned.

Nor is a purely dynamic nominalism any more possible. To be sure, truth deals with a world of change. But change need not be chance or absolute discontinuity of process. In so far as such is the case, truth of course is impossible. Change may be circular, or practically so; and it is a world with a certain uniformity of characteristics, however much it may change, with which truth must deal. It is only in so far as our world of experience can be taken as constant, that we can have science, though of course such a statement would be meaningless if we did not deal with a world of change.

The law of consistency always has to do with meanings. The meanings may be abstract or hypothetical merely, and our interest may be in their formal relations. Or the meanings may refer to qualities and relations in concrete experience, and so may be concerned with existence. But in any case the law of consistency refers to the identity of meaning, and holds that, from an identical content, identical consequences must follow; so that if certain consequences follow from *M* in the case of *P*, the same consequences must follow from *M* the case of *S*.

The law of consistency applied to the concrete meanings of experience – qualities, relations, or whatever they may be – means that you cannot take the same *fact* as *A* and not-*A*. A thing cannot be taken as having the quality of *A* and the quality of not-*A*, white and not-white, in the same respect. It does not deal with the question whether a thing *can have* the quality *A* and not-*A* in the same respect. The law of identity is forced upon us irrespective of the object, though inasmuch as reality is for us what it must be taken as, in the procedure of experience, we naturally extend the law of our thinking to things as well. In this there can be no harm, if we know what we are doing and are not postulating some occult harmony to cover up our previous dualism of thought and things, created by our own assumptions. One thing is certain, the world of experienced things is to some extent describable, and so must have some degree of identity.

That *A* is not not-*A*, that sour is not sweet or any other quality within the universe of taste, involves no contradiction. They can still hang together within one system. In fact there can be no system, if there is not difference. Being and not-being, as pure abstractions, do not imply each other. They are exclusive. But as pure abstractions they are also indistinguishable. They can have meaning only within a context. And when we really develop their

meaning, instead of bandying terms, we find that they hang together by their edges – that we cannot define one without implying the other within a system of meaning which posits them as aspects of itself. Bradley would argue that, since *A* cannot possibly be not-*A*, therefore they cannot be related in any manner. For suppose they were like in any way. Then in so far they must be identical or partake of a common term. This leads to an infinite regress. But what is this but playing with terms? Of course, if *A* and not-*A* be made exclusive by definition, they cannot belong together. But that does not prevent our actual *A* and *B*, as experienced, from belonging together within a system, though perhaps not always one of logical implication, as Hegel thought. Experience is not chopped up with a hatchet, not made up of isolated abstractions. As immediate, the qualities of experience are unique. But as immediate they are neither here nor there, neither this nor that, neither more nor less – not truth. It is because these facts are capable of being sorted into series and classes, on the basis of degree or kind, that we have science. And this distinguishing of degrees or kinds, identities or differences in the world of individual facts, does not seem to disrupt. It contradicts neither their existential nor their appreciative unity.

Two aspects are involved in the concept of consistency, as I am using it: First, that terms must have an identical meaning, must be taken as the same throughout the argument. Otherwise we shall not be talking about the same thing, and so shall be guilty of the fallacy of four terms. This use of the term consistency is closely bound up with the other aspect: namely, that from identical characteristics follow identical consequences, whether we deal with relations or qualities, or whatever the selected content may be, and whether the individual facts be the same, or we be dealing with new groups of facts. A case of this would be Euclid's postulate: "Things equal to the same thing are equal to each other." Stated in a more generic form: If any individuals or groups of individuals are identical in some respect, they can be exchanged so far as that characteristic is concerned. This is equally involved in deductive and inductive inferences. What we must be careful about in each case is to isolate or distribute the identity, to see not merely that there is identity in the situations dealt with, but that it is significant or relevant identity – identity in the same respect, *i.e.*, that it pertains to the consequences which we try to deduce. This is reduced to a technique in the syllogism by rules such as, the middle term must be distributed at least once, no term must be distributed in the conclusion which is not distributed in the premises, there must not be more than three terms, and both premises cannot be particular or negative. As regards causal relations the technique of discovering this identity has been systematized in Mill's canons, the ideal of which is the method of difference, which means precisely a distributed identity. We thus proceed to sort our facts into classes and series with determinate characteristics and predictability. The success may be varied, and even with cumulative coöperation and special-

ization, must necessarily be slow, considering the complexity of our world. Sometimes the result of scientific investigation is simplification of hypothesis, as in reducing magnetism and light to electricity. Again, new and unforeseen data come to our ken, necessitating fresh assorting, as in the recent discovery of the radioactive elements. But the progress of science, physical and psychological, is evidence to how great an extent the world of our experience lends itself to conceptual manipulation.

A great deal has been said justly against substituting mere analogy for proof, as the human mind in its laziness so often does. This must not blind us to the fact, however, that we must proceed by analogy – the seeming identity in the new set of facts with situations that we have tabulated and learned to meet in past experience. Newton's theory of gravitation, Darwin's theory of the origin of species, are splendid instances of framing hypotheses on the basis of analogy and with successful outcome. We must be careful, however, to make certain, by observation and experiment, that the likeness is *relevant* likeness – that the consequences which we try to predict follow from the identical characters which we have selected. Two men may be identical in being tall or black or Italian, but it does not follow that you can predict from one to the other as regards reliability, though that is the way we often implicitly proceed.

As the law of consistency means that an object of experience must be taken as the same (quality or relation) in the same respect; or, expressing it negatively, that an object cannot have different predicates in the same respect. This will be seen to include what Lotze has called "the disjunctive law of thought," a species of which, in the case of only two alternatives, would be the so-called law of excluded middle. To use a concrete instance: A rose *a priori* may be qualified by any one of a number of colors, but as a matter of fact it can be taken only as having one color in the same respect. And if it possesses one, for example, red, it cannot possess any of the other colors at that point. Whether you artificially dichotomize your universe of color as red and not-red for the purpose, or state the actual disjunction of alternatives possible, the result is the same. An object cannot both be taken as having a quality and as having a different quality in the same respect. The "disjunctive law" is hardly even a corollary. It is rather the explicit statement of the law of consistency, as previously used.

If the traditional laws must be regarded as different emphases at most of the same principle, they have their meaning, nevertheless, as psychological stages in making explicit the law of consistency. From this point of view the consciousness that *A* must be taken as *A*, in a universe of discourse, is less distinct than the consciousness that *A* cannot be taken as not-*A*. But the full significance of the law of consistency is expressed in the "disjunctive law," viz., that our universe of discourse must be capable of such disjunction that *A* can be distinguished from *B* and every other possible predicate in the same

respect – only one of which can be taken as qualifying the subject and thus be predicated in distinction from the rest.

As corollaries or implications of the law of consistency, we would have the axiom that what can be predicated, whether affirmed or denied, of a kind can also be predicated of that kind's kind, which is so vital in all our deductive procedure. And also that what is true of one group of facts is true of another group, if the practical consequences follow from characteristics which the groups have in common. And thus we can extend our knowledge by analogy to new cases and test its application there.

2. The Law of Totality

But though we are able thus to establish kinds or systems of fact, with their definite connections and predictability *in suo genere*, the question still remains whether these systems cohere into a whole, hang together as kinds, or whether perhaps our world is made up of disparate or parallel systems, whether two or infinite in number. Now to be knowable it will be seen that somehow the ,various systems must hang together at least with our cognitive purposes. We must have systematic connection in the large (*in dem Grossen*), as well as unique determination within the one kind of series (*in dem Kleinen*). Taking number as one illustration, not only must the various series, finite and trans-finite, be self-consistent, but we also demand that they shall form a complete whole. Now this postulate of systematic connection in the large, I would call the law of totality.

This is broader than Leibniz's law of sufficient reason: Nothing happens without a reason why it should be so rather than otherwise. The law of totality does not emphasize teleological connection as over against causal, as has generally been the use of the law of sufficient reason. It merely emphasizes that facts do not exist as isolated individuals or isolated groups in our experience, but belong with other facts; that reality, as we know it, hangs together by its edges, so that we can pass from one fact to another, either directly or by intermediaries; and that only so can we know it. It does not mean that every fact makes a difference to every other; that our fancies alter our gravitational relations to the Milky Way. This would be impossible to show. On the contrary, we know that some facts seem to make no direct difference to a given group of other facts; and some make a certain kind of difference only under certain conditions of intensity or complexity. It makes no difference to a color in what part of a space or time series it is located, whether perceived yesterday or to-day, here or in China, given the same concrete setting. But the number of vibrations per second do make a difference. Even here, however, on account of the structural conditions, a certain intensity of vibration is required to perceive light at all, and a certain number of vibrations per second must be added to perceive another kind of

light. Experience, as we can take account of it, does not proceed by infinitesimal transitions, but by finite drops or bucket fulls. The law means that facts possess such uniformities or similarities that we can pass from one to another, under determinate conditions, if not immediately, through a series of intermediaries. If my thought does not directly affect other bodies in space, it may do so indirectly through the difference it makes to my own body. But, by some edges, some common attribute, all the parts of our world hang together. Mind must make a difference, under determinate conditions, to mind, and body to body, and mind to body and body to mind, in so far as they are parts of our experience and known by our experience.

The constitution of the human mind makes the causal category a pervasive one. To know our world means that its various objects can make a difference either directly or indirectly to our minds. This, in the case of the physical world, means a causal difference. To speak of physical changes as parallel to thought would mean that the mind can take account of objective existences that make no difference to it, which is absurd. That our ideally posited world of objects makes a difference to our purposes requires no elucidation. Thus widely interpreted, the law of totality means that the world with which knowledge is concerned cannot exist in compartments. It is a command to look for connection. In a certain sense it may be taken as equivalent to Spinoza's conception of substance, without assuming *a priori* that "the order and connection of ideas is the same as the order and connection of things." We have to do here only with things as experienced. We might, however, agree to Spinoza's axiom that "things which have nothing in common cannot be understood, the one by means of the other; the conception of one does not involve the conception of the other" – meaning by "in common" merely that the things must be capable of making a difference to each other under certain conditions, and especially, directly or indirectly, to our cognitive purposes. We cannot know universes split off from our own, if such were existentially possible.

In spite, however, of Spinoza's insistence upon the unity of the one substance, he left us two disparate parallel systems which can make no difference to each other, have no common attribute – the world of thought and the world of extension. Our concern here is not with the metaphysical possibility of such a conception. But for epistemological purposes, we must assume not merely that the universe can be sorted into kinds, but that these kinds somehow hang together, that one part of our experience coheres with another part, either directly or by means of intermediaries. Only in such a world would social objects be possible. Facts thus have not merely a unique determination within their own special system, but have a universal reference, cohering as a whole. And this is what I mean by the law of totality.

And how do they cohere? I can conceive of only two ways: either as cause and effect, or as means within a purpose, logical, ethical, or esthetic. And it

is not necessary for epistemological purposes, whether it is for metaphysical or not, to reduce these to one. It is not enough that facts are together in one space and one time. They might be thus together and yet exist in compartments. Space and time do not unify. On the contrary the same presupposition of totality applies to our space and time systems. We assume the unity of space on the basis of the law of totality, *i.e.*, because we believe that our universe of facts, spread out in space, hangs together. And so with the unity of our social time construction or history. Empirically we do come upon functionally dissociated time series in experience, as in automatic writing and trance, but they are cognitive realities only when connection is established for some subject. Facts must run into each other some way, causally or teleologically, to make the unity required for cognitive purposes. And as all teleological unities are also psychological events, therefore all facts must in the last analysis be causally conceived, according to some definite relationship, as objects of knowledge.

Nor does the law of totality mean merely that the facts of experience are a collection of such a kind that we can use connective symbols as *and* or *with* or *on*, etc.; not merely that we are conscious of the facts together, which we are only to a small extent, but that facts make a difference to some other facts, become confluent with some other parts of experience, in a systematic way. If knowable, they are not merely lumped as *ands* and *withs*, but strung with identities which we can disentangle either causally or teleologically. This we postulate at the very outset of logical investigation. Only in this way are consequences predictable, formally or materially. Whether the laws of thought are coërcive over things or not, they hold for our experience of things, actual and possible. And that is all that is logically important. The form of experience at any rate is predetermined.

Because we must assume that facts, in order to be known, must be capable of making a difference to other facts and so, either mediately or immediately, to our powers of knowing, it does not follow that we must assume that facts, in advance of being known, must be strung on the unity of thought. Facts in order to become *known* must be strung upon our hypotheses, become a part of our purposes, but that does not prove that they can only *exist* as thus strung. It is through such stringing that facts come to have their *significance* for our human experience, but that does not prove that they then begin to *exist* or that thus they must exist in a larger mind. Facts satisfy the law of totality when they are capable of making some difference to our purposes under definable conditions. This is quite different from holding that, because we can string things on our unity of apperception, therefore they must already be part of a transcendental unity of thought.

3. The Law of Duality, or the Presupposition of the Subject-object Relation

This is involved in all thinking; and the attempt to state the subject as object or vice versa, for thought purposes, gives rise to a paradoxical infinite which is not a progress toward a limit, but which simply means that you cannot transcend the subject-object relation while you remain within the concept of thought. This paradoxical answer resembles the one you get in number when you ask what number is less than the least conceivable fraction. To which the answer is: zero, which is not a number at all, and so beyond the series of fractions, The difference is that the conception of an infinite series in the case of number has a warrant in the progress toward a limit, which is not the case in the subject-object relation. Here nothing is gained by the repetition, once you have grasped the law that in every judgment, including the reflection upon itself, the subject-object relation is involved. You do not get a thought, at infinity, which is neither subject nor object.

A good deal has been said about the self-representative character of thought and its supposedly implied infinite. Now, it is quite true that the proposition, no subject without an object, as a law of thought, must be self-applicable, *i.e.*, the judgment, as regards the subject-object relation of thought, itself involves the sub-object relation. Like all true presuppositions of thought, the subject-object presupposition is circular, Thought activity always means the discovery of the relation of a selected content to a system; and to this the reflection upon the subject-object character is no exception. We simply become conscious of the fact that the self-representative judgment is an instance of the universally representative character of thought and differs in no wise, so far as the application of this law is concerned, from any other judgment.

Now, thanks to language, this representative statement, whether self-representative or other-representative, can be repeated upon itself to infinity. And this, no doubt, has its own value as a logical sport, whether in the philosophy of number or in other speculations; but it does not in anywise clarify the nature of thought. For purposes of epistemology, the self-representative character of thought simply means that the subject-object relation as a presupposition of thought is self-applicable. It certainly does not prove that truth is an infinite series.

Neither does the universality of the subject-object relation in all our *thinking* prove that it must hold universally for *existence*; that because we cannot *think* an object without a subject, therefore all thinkable *reality* must be involved in the circle of this subject-object relation, ergo: all reality must be a spiritual or reflective unity. This has been a favorite argument for idealism and is certainly a short cut. But is it valid? We must remember that the subject-object presupposition only holds for our *thinking* of reality. It

can only be a presupposition therefore for reality which thinks. Our reflecting upon the stone does not necessarily make the stone reflective, and so does not necessarily sweep the real stone within the subject-object circle of our thought, in the sense of its existence being conditioned by its being known. What parts of reality think and what do not think must be decided upon evidence, and not by any *a priori* epistemological presuppositions. All we can show is that these must hold for *thinking beings*, that they are presupposed in our thinking, and that our denial of them affirms them. But we cannot show *a priori* what beings *are* thinking beings or that the universe as a whole is a thinking animal.

The relation of the referent to the referatum, of subject and object, in the judgment relation of the living thought process is different from the reference within a logical context, taken as abstracted from the real subject. This has often been lost sight of in the definition of the judgment. The meaning of the proposition, however complex its internal organization may be, only figures as a judgment, when it is taken up into the active thought context at the time. This active context of interest is the real subject or referent; the proposition or ready-made judgment, as taken account of in formal logic, is in this relation the referatum. Not the proposition as interpreted by the cognitive moment, but the proposition as the vehicle of the active meaning at the time, is the symbol of the judgment. The cold-storage proposition *was* a judgment, but is now merely an object of thought, comparable to any other object, such as gravitational relations in space.

4. The Law of Finitude

So far from thought being infinite in character, I shall try to show that thought or truth must always be finite. We have seen that thought is in nature relational; that it universally means the active selecting and assimilating of a datum by an apperceptive system which does the selecting and relating. Now both the content selected and the system within which it is to be related or defined must be finite in character. We must generalize from certain clear and distinct finite characteristics. I will use geometry, a purely formal science, to make my point clear. I quote from Russell regarding the determination of points and their relations: "Any two points determine a unique figure, called a straight line, and three in general determine a figure, the plane. Any four determine a corresponding figure of three dimensions and for aught that appears to the contrary the same may be true of any number of points. But this process comes to an end, sooner or later, with some number of points which determine the whole of space. For if this were not the case, no number of relations of a point to a collection of given points could ever determine its relation to fresh points, and geometry would be impossible."[1] And again in speaking of dimensions:

[1] "Foundations of Geometry," p. 132.

"The number of relations required must be finite, since an infinite number of dimensions would be practically impossible to determine."[2]

This law of finitude has been generalized for the whole field of mathematical science by so great a mathematician as D. Hilbert: "When we are engaged in investigating the foundations of a science, we must set up a system of axioms, which contains an exact and complete description of the relations subsisting between the elementary ideas of that science. The axioms so set up are at the same time the definitions of those elementary ideas; and no statement within the realm of the science whose foundation we are testing is held to be correct, unless it can be deduced from those axioms by a finite number of logical steps."[3]

That we always base our concepts or laws upon the examination of finite facts and their finite relations was definitely recognized by Aristotle: "If the kinds of causes had been infinite in number, then also knowledge would have been impossible; for we think we know, only when we have ascertained all the causes, but that which is infinite by addition cannot be gone through in finite time."[4] And in the same connection he shows that even if there existed an infinite, the concept of the infinite could not be infinite. For the same reason both Plato and Aristotle recognized that there could be no truth of absolute flux or absolute chance. It is only flux that repeats itself under describable conditions, variety with finite characteristics, that can be reduced to science.

To be sure the law may repeat itself in an endless number of instances; there may be no last term in the series. Such series abound in mathematics. But, in such cases, it is not the potential infinity of the steps which constitutes knowledge. Clearly, a generalization from enumeration would be a contradiction, if we assume infinite instances. The concept of the series is based upon the fact that the steps repeat themselves according to certain finite characteristics or laws. It is this, the identical or universal element, with which truth is concerned, not with the repetition. In fact, once the law of the series has been discovered, the repetition becomes useless. You can then take the series as completed. There would be no virtue in repeating the series, 1 + ? + ?, etc., after discovering its limiting term or its sum, whichever you may be interested in. An infinite number is contradictory, because $n + 1$ is the nature of number. This law is based upon the number process as actually observed. The unpredictable character of number, outside of its general law, is well known, because in each case we must proceed by induction from individual instances and observe their relations.

[3] Translation by Dr. Mary Winston Newson in the *Bulletin of the American Mathematical Society*, July, 1902.

[4] End of Ch. II, Bk. II, "Metaphysics," translation by Ross.

The infinite, in the case of thought, arises from not recognizing the presuppositions of thought; for example, subject and object. The infinite reflective series does not solve the problem. It can only bring the presupposition involved to light. The infinite cannot then be regarded as of the nature of thought. It is merely a result of reflecting upon the nature of a reflective system. It is posited by thought as its logical sport. It has nothing to do with the laws or validity of thought. It shows that thought is dependent upon the larger will which sets the game. Knowing knowledge does not mean that we must know in advance of knowledge, but that we must analyze the presuppositions of knowledge. It is the circular character of the presuppositions of truth, looked at as abstract truth, that gives rise to the apparent infinity of truth. But the infinity is only apparent. That the law of identity or any other *a priori* postulate is epistemologically circular is as clear at the outset as it would be after endless repetitions. We need only become conscious of its *a priori* character as a presupposition of truth. To be sure, it applies to itself as a proposition and to the reflection upon this application, etc., but nothing is gained by such a repetition. It is a disease of language.

The infinity of Plato's Parmenides and of Bradley is a paradox created by definition – by taking thought as abstractions, mutually exclusive, and then attempting to bring them together. In the infinite of the Parmenides, for example, you have no true limit, though there is no end to the series. If terms are like, they must partake of or belong to the idea of absolute likeness; but in this case the term must be like the idea and the idea like the term; and this likeness must be due to their partaking in an idea of likeness and so on to infinity. Otherness would do as well as likeness. In fact any relation, taken as an abstraction, will illustrate how contradictory it becomes. Thus the one shows itself other than the other, etc. In Bradley, you have a similar infinite as regards qualities and relations. Here, too, there is no limit or progress in the series. If you start with disparate, independent qualities, then any relation which tries to relate them must have something in common with each of the terms; in that case it disrupts and must in turn be related, etc., *ad infinitum*.[5] But the infinite repetition offers no solution. It simply shows that such a definition of qualities makes relations impossible, which ought to be clear at the outset.

In order to apply the conception of the infinite to knowledge in a significant way, it is necessary not only to show that, so far as knowledge is concerned, the dualism of subject and object, of system and datum, is insuperable and, therefore, that no finite steps can solve it, but it is necessary to show that there is progress toward a limit and what this limit is. Now, in knowledge, the datum to be organized may be considered as capable of greater and greater systematization, and thus growing smaller as outstanding raw material. But

[5] For a recent statement of Mr. Bradley's position, see *Mind*, October, 1909, pp. 494 ff.

this does not prove that knowledge is infinite. Further, it is true that the limit of the thought process, its *rationale*, cannot be reached on the level of thought, for though all other data were organized, all other problems solved – set by the nature of the content or by the free play of thought – when the last surd has yielded up its enigma to the progressive system of knowledge, there remains the problem of thought itself. Thought makes itself the pure content of its own reflections. And here it discovers a limit beyond itself. For thought cannot answer the question: 'why thought?' Or why does thought have this constitution and no other? Why this search for wholeness? Or stating it in relational terms: Granting that we may be able to weave our relations into ever larger and more comprehensive relations, the minor classes into still larger classes, how can we define a system of relations which is not in turn relative to a larger system, a class which is not itself a class? Here you come upon a limit of the process, which like the number zero or the zero of quantity lies outside the process itself, viz., in the purposive will which chooses to realize itself in this way, chooses this form of activity – the will to think. But there is nothing to show that this zero lies at infinity. It is rather the purpose within which thought moves, the end for which it exists. Thought has reached the Canaan of its progress. But, like Moses of old, it cannot enter. This is the land of faith.

WHAT PRAGMATISM IS AND IS NOT

John Elof Boodin. "What Pragmatism Is and Is Not." *Truth and Reality: An Introduction to the Theory of Knowledge* (New York: Macmillan, 1911), chap. 10, pp. 186–199.

The confusion in regard to pragmatism by its critics on the one hand and the variety of doctrines included under that term by its defenders on the other hand, make it highly desirable for all concerned that there should be a definite understanding as to what pragmatism means. Failing such an understanding, the term pragmatism should be dropped out of the vocabulary of philosophy. This would be a pity, as the term short-hands a good deal of circumlocution and has already been widely used. What place pragmatism shall ultimately come to have as regards various schools of epistemology or metaphysics, whether the old labels of idealist and realist, spiritualist and materialist, empiricist and apriorist, can still be retained, is of little consequence except to those who must set their house in order, providing that pragmatism as a doctrine must be reckoned with.

In the first place, pragmatism as a doctrine is so simple and as old as a matter of scientific procedure that it is impossible to understand why so much dust should have been raised about it by its opponents. It is simply the application of the ordinary method of the scientific testing of a hypothesis to philosophic hypotheses as well. It is certainly high time that philosophy, in many respects the oldest of the sciences, should take on scientific definiteness and severity or else regard itself as a department of poetry.

Now pragmatism, as so often stated, holds that you cannot test the truth of a hypothesis or judgment independent of conduct. The truth of an idea or plan must be tested by the procedure to which it leads. You can, of course, insist with the medieval critics of astronomy that there must be seven planets because there are seven days in the week, etc., *i.e.*, from the *a priori* fitness of things, but the curiosity upon which science is based always insists on trying the assumption; and if experience indicates more planets, we revise the hypothesis to fit the facts. This is the "practical" testing of a doctrine in science.

The testing of a doctrine in terms of conduct, or comparing the anticipated consequences with the consequences to which it leads in being carried out, need not always mean material consequences. There is a conduct of the understanding as well as a conduct involving certain perceptual events as its

outcome. The procedure may be entirely of a logical kind as in formal logic and pure mathematics. But here, too, the idea is true only as it terminates consistently in its intended result. The consequences must be shown to follow from the definitions and not from assumptions or intuitions surreptitiously introduced in the course of the argument. The rules of logic, as the rules of ethics, have been adopted for their convenience in conduct.

Common sense and intuition may short-hand our scientific methods, and are valuable in many cases, but they are not truth, in the scientific sense, until the conclusions thus arrived at are systematically tested in the actual procedure of experience.

We sometimes have to choose between different rules or concepts. In this case we must ask ourselves what difference it will make if I choose one rather than another method of procedure. It may make no ultimate difference. The same problem can be solved by plain arithmetic or by algebra. Both solutions are equally true. Only habit and convenience, therefore, can decide between them. When two roads lead to the place to which I want to go, other things being equal, I take the most economic road. Esthetic or other motives, however, may influence me, besides the mere desire of arriving, and so I may choose the longest route. And so in the choice of hypotheses. But in any case the hypothesis is verified only as it terminates in the intended result; as its ideal consequences tally with the conditions which I have set myself to meet, whether purely logical or perceptual as well.

Now I certainly have a right to profit by previous experience, whether my own or that of others. I may have faith in a chart of the road already provided, without going through the trouble of mapping the routes in that particular neighborhood again. But this deductive truth rests no less on conduct; and if it should fail, in the process of adjustment, to satisfy the demands of further conduct or experience, it must be revised, however venerable or distinguished may be its ancestry. Truth about reality as a whole, or any part of it, however abstract, consists in the differences that reality makes to our reflective purposes in their historic realization.

To ask, therefore, whether a statement is true is equivalent to asking: What must we take the selected object as, in the procedure of experience? This is as true of the formula, $2 + 2 = 4$, as of the proposition, Socrates is mortal. For some purposes taking two pounds twice is equivalent to taking four pounds once. This obviously is not always so. Taking two women one hundred pounds each is not equivalent to taking one woman two hundred pounds if the purpose be marriage. In the former case you will be thrown into jail for bigamy. The intuitional character of the formula is due to the fact that we have forgotten the concrete procedure, the beads, for example, that were used by the primary teacher to overcome our stolid incredulity. The only way that you can know that you know is by trying out your knowledge, and even then, owing to the finitude of our nature and the complexity of reality, our certainty

is decidedly empirical. We no doubt confront the environment with all sorts of tendencies or categories, more numerous than Kant's table, but truth they are not, until they are reflectively tried out, in the procedure of experience.

But is not truth agreement with reality? the hard-headed critic always comes back. Yes, certainly, *i.e.*, with the reality which we intend, which may be the constitution of number or of a chemical compound. We rarely ever aim at reality as a whole, any more than we aim at a bear as a whole when shooting at him. The subject of our judgments is almost always a selected part of reality, not reality in general. But the pragmatist doctrine, so far from denying that truth is agreement with its intended reality, has for its purpose to make explicit what we mean by such agreement. And what we mean is what science always has insisted, viz., that the consequences which follow from the hypothesis, or the constitution of the object *as we have conceived it* on the basis of past experience, shall tally with the consequences *in dealing with the object*, or with further experience, formal or empirical, according to the problem set. There is no such thing as agreement in the abstract; no way of finding out the truth of an idea by merely examining its eternal fitness in general. It must, in order to be true, fit its intended constitution, as Royce has so splendidly shown, and this can only be found out by observing the results of our experiment, by the tallying of our hypothesis with our systematic observations. The data thus caught, simplified and organized through the network of our concepts, which in turn have been progressively modified to meet the demands of the data, is what we mean by the laws of science. Whatever reality may be, science is a systematic sorting of experience in the realization of our interests.

I suspect, however, that what has given rise to this long and confused controversy is not pragmatism as an epistemological theory, but the various epistemological and metaphysical consequences which some of the "pragmatists" have arrived at, supposedly by the pragmatic criterion, and which have been included by them and their critics under the general heading of pragmatism. Of course, if you include any professed pragmatist's results under pragmatism, then you will have an indefinite number of pragmatisms with hopeless confusion of the epistemological issue.[1] Just because a professed pragmatist, even William James, happens to hold a doctrine does not necessarily make it part of the theory of pragmatism. His philosophic results would have to be tested by the pragmatic criterion, quite irrespective of his having subscribed to it. Even the best people's conduct does not always agree

[1] Lovejoy's "Thirteen Pragmatisms" seem a petty allowance, when you consider the variety of human nature and the number of possible applications of the pragmatic method. But such analysis has been wholesome in exposing the confusions in the pragmatist camp and thus clarifying the main issue. See *Jour. Phil. Psych. and Sci. Meth.*, Vol. V, Nos. 1 and 2.

with their ideals. And the pragmatic criterion is an epistemological ideal, which we finites can, only by cumulative striving, if ultimately, realize.

Let us see briefly now what pragmatism is not. In the first place pragmatism does not involve that the true and the useful always coincide. Such an *a priori* assumption about the universe is anything but pragmatic. Truth may, of course, turn out to be useful. I would not say with a German scientist that the best part of science is *dass es gar nicht anwendbar ist*. The utilitarian motive has often been important in the investigation of truth, sometimes on the part of the investigators, but more often in the material promotion of investigation. It is true, however, that the most important investigations in pure science, such as the beautiful researches in light and electricity, were carried on without reference to their utilitarian consequences by people inspired by a divine madness to discover the hidden harmony of things; and their results were finally patented by people who reaped where they had not sown. But whether researches are useful or not, their usefulness does not make them true. On the whole we are doubtless better able to adjust ourselves to an environment because we know more about it, can respond to its characteristics, though in limited, pathological cases ignorance and deception may be more useful than truth. But the statement that truth is, on the whole, useful is a conclusion and not a part of pragmatism as an epistemological criterion. Whether it is a legitimate pragmatic result, any one is free to test, where all hypotheses must be tested, in the procedure of experience.

In the second place, pragmatism is not equivalent to humanism. No doubt it is true, so far as we are concerned, that reality must pass through human nature to be known. We humans know reality by the differences it makes to our human, specific, reflective purposes in their attempt at realization. But it is not our being human that makes our hypotheses come true; it is their tallying with the constitution of the object aimed at, as it appears in further experience. And there is nothing to show that this experience, whether on its logical or perceptual side, is peculiarly human. The weight, or color, or size or position of a thing is not peculiarly human as distinct from other animals. A "dog-faced baboon," so far as we know, has the same sort of perceptions that we have, and is subject to the same laws of association. If a dog-faced baboon or a tadpole should construct hypotheses or their equivalents, they would have to be verified in the same pragmatic way as human hypotheses are. It matters not what sort of finite being tries to arrive at truth, whether man, baboon, or angel, the test of truth, so far as we can see, would be the same.

If what is intended is the statement that the nature of reality is made over in knowing it and that therefore we are limited to the charmed circle of experience, this, too, is an unpragmatic assumption. While it is a mere circle to say that we can know reality only as it appears in cognitive experience, or for what it must be taken as, it is a gratuitous assumption to insist that what

reality is known-as, is contrary to what reality is, that the weights and distances and masses of things exist only as we humans take account of them. When we take account of them, they have *meaning* for us, but our taking account of the qualities of things at all is generally forced upon us by their existence, which we must meet in order properly to adjust ourselves. At least it is not pragmatism to decide *a priori* that things are not what they seem.

May there not be cognitive beings superior to us humans? Or are the humanists absolutely convinced that we humans are the only cognitive beings in the universe? That certainly is no part of the pragmatic theory of truth; but, even if true, it is not being human that makes a proposition true, but its termination in the intended facts.

Is pragmatism, as a theory of truth, committed to the instrumental point of view as regards concepts? Not in the sense that truth exists solely for the sake of satisfying certain demands extraneous to itself, for example the biological end of adjustment. Truth sometimes finds its inspiration in such practical demands, but it sometimes finds its motive in scientific curiosity. In any case the test must be the same. Truth is always teleological, because it exists for the sake of a relation to a larger whole, but this relation need not be instrumental in the narrow sense that truth is an extraneous tool, like a knife, to be judged by its mere success. False ideas may be temporarily successful. Truth as a matter of fact must always be imitative of its object to a certain extent. It can never be conventional in its *content*, however conventional our *symbols* may be. In the case of knowing a system of truth it must be imitative of the meaning of the object; in the case of thing-objects it must be imitative of certain qualities of the object. Inasmuch as our finite truth is not exhaustive, but always implies a more, a larger constitution to be investigated, it must be regarded, in so far, as instrumental to its own completion, a means to its own more comprehensive end.

Can the pragmatic criterion be stated in terms of satisfaction? That depends upon what sort of satisfaction we mean. No doubt the seeking for truth has its own hedonic tone, according to its success or failure. The satisfaction, so far as the truth interest is concerned, is the tone accompanying the testing of the hypothesis in procedure, so far as that special intent is concerned. But the truth satisfaction may run counter to any moral or esthetic satisfaction in the particular case. It may consist in the discovery that the friend we had backed has involved us in financial failure, that the picture we had bought from the catalogue description is anything but beautiful. But we are no longer uncertain as regards the truth. Our restlessness, so far as that particular curiosity is concerned, has come to an end. And this satisfaction may sometimes be strong, even when the practical outcome is against us. The rejected lover gets some peace of mind from knowing the truth as to his failure. But this is hardly the satisfaction of winning his suit.

Is pragmatism realistic? Only so far as it intends a world beyond our finite cognitive purposes. The finite fragmentary intent must find its reality or

correction in a larger whole. I do not know of any striving for truth which is not realistic in this sense. How could it be a striving for truth otherwise? But obviously a criterion of truth must be unbiased at the outset as regards the epistemological or metaphysical result of its application. The reality we seek to know may ultimately be more experience – yes, we must be willing to have it turn out to be an absolute unity of thought, if the procedure of truth leads that way. But pragmatism neither assumes at the outset that the object in order to make any difference to the cognitive purpose must itself be experience, nor does it assume *a priori* that reality cannot possibly be what it is known as being, because external to experience. What reality is, what differences it can make, is precisely to be found out. The constitution of the universe is idealistic or materialistic, monistic or pluralistic, according as we must take it, as the outcome of the pragmatic test. But we must all start with the same criterion, else there can be no discussion of truth.

Truth is systematic meaning, systematic experience about the object. This meaning, in case we are striving to know other experience, must be identical with the content of the object; but the qualities of an object which is not experience may become content for us through perception. In any case truth is our systematic *percipi*, as it is revealed in our specific procedure, whatever the metaphysical character of the object may turn out to be. We have no right to take for granted that what is to be known is more content, independent of our knowing, with which our preformed guess can be accidentally identical and so be called true in advance of verification.

It is difficult for me to understand what is meant by unverified truths – unverified science, truths which no one knows to be true, for if any one knows them to be true – God, or man, or monkey, they have fulfilled the pragmatic test. They are seen to terminate or find their completion in the intended object. If a proposition has no systematic basis in experience, we speak of it as a mere guess. As that brilliant pragmatist, Xenophanes, puts it, "All are free to guess" and, "These are guesses something like the truth, ... but by seeking they gradually find out what is better." In Xenophanes's time there was but little cumulated scientific observation. Hence he is naturally impressed with the guess character of his statements about the universe. When a supposition is based upon analogy and previous scientific observation, we call it an hypothesis, but it is only as the hypothesis is fully tested in terms of the intended facts that we call it truth. Truth, therefore, so far as we finite seekers are concerned, is a limit which we are far from having realized. Whether we can realize it or not, only the historical outcome of the pragmatic test can prove. It is certainly unpragmatic to say in advance that truth is unrealizable. In the meantime we have our provisional "truths."

I suppose the reason that some have insisted upon propositions being true in advance of being tested is that in individual experience, especially in an advanced stage of science, we find a large body of social truths, which we can

take, for practical purposes, as ready-made. We find that truths exist independent of our individual verification, and then some assume that they exist independent of all verification. Seeing the agreement of the hypothesis of gravitation with its intended facts, they insist that the hypothesis must be true in advance of the discovered agreement, as though truth could be a guess *in vacuo*. What they mean is that reality has a constitution in advance of our investigations and that so far as our cognitive nature is concerned the qualities of reality are not created, but discovered. Whether they are created through our volitional nature, or exist independent of our act or positing, is a question which the application of the pragmatic method alone can determine. But all this controversy about preëxisting truths is a lexicographical one and would be over if we recognized the established philosophic usage, as old as Xenophanes, that truth is systematic meaning, corrected and completed in its intended reality.

If we state truth thus, there can be no ultimate difference between truth and the test of truth. A proposition is *proven* to be true because it terminates in its intended object, imitates this either as regards its inner content or as regards its qualities. But it *is* true for the same reason. What makes the test of truth seem something different from the truth itself is that in the process of verification the test seems external to the intent of thought. It seems to happen to the idea in a more or less accidental way. But this is a superficial way of looking at the process of discovery. For the facts only happen to the intent of thought *because we are seeking them*, however much our meaning may have to be corrected in the process. The test is our further experience about the object *as selected* by the intent. But the intent is not, taken by itself, the truth, any more than the consequences of further experience are the truth taken as external happenings. It is the intent as terminating in the selected facts which constitutes the truth. And this termination is the test of truth, or the intent as tested constitutes the truth.

Is pragmatism a theory of empiricism as opposed to rationalism and *a priorism*? No, pragmatism is not committed to any *a priori* doctrine of the origin of ideas or their connection. It is not committed to Hume's association theory any more than to Plato's doctrine of recollection from previous existence. Pragmatism may be said to agree with rationalism in holding that truth has a formal side. A hypothesis or system must be internally consistent. But pragmatism insists that this is not sufficient: there must also be external agreement, or agreement of the hypothesis intended facts. As regards the other historic antithesis, that of empiricism and *a priorism*, pragmatism is equally non-committal. It is a theory of the test of truth, not of the origin of its categories or postulates. Whatever demands or tendencies are inherited, they must be consciously tried out in experience as regards their agreement with reality before they can be called true. The categories might originate by use-inheritance, by natural selection, by divine implanting, or by mystical

intuition, so far as pragmatism as a theory of truth is concerned. The question is: Will they work in simplifying experience and meeting the character of the environment? The theory of their origin must itself be subjected to the pragmatic test.

Is pragmatism at the outset committed to time and chance as the ultimate character of reality and, therefore, to the impossibility of any final truth? This again is a theory to be tested by its pragmatic outcome. *A priori*, eternalism may be the outcome of pragmatism as well as dynamism; or perhaps partly the one, partly the other. Because the discovery of truth is a temporal process, it does not follow that truth relation as discovered are temporal. The truth 2 + 2 = 4 may be eternal, however long was the evolution which led to its discovery. At any rate, there can be no such thing as pragmatic dogmatism.

A professed pragmatist may of course hold any of these doctrines, and a large number of them, either as his individual application of the pragmatic test or for other reasons. He may also, like me, be an Episcopalian, a free-trader, etc. Do all the doctrines and practices of the Episcopal Church become pragmatisms when a pragmatist belongs? I have known pragmatists to drink beer, to attend dime theatres, and even to swear. Are all such practices with their implied damnable theories of life therefore pragmatisms? And do they also come under *Scepticismus*, as the German critics would say? God forbid. It makes one's flesh fairly creep to think of all these uncanny associations – these sins on the part of our clever young critics, committed in the name of pragmatism. But are they not, after all, primarily sins against formal logic? A is a free-trader. A is a pragmatist. Therefore all pragmatists are free-traders. That looks very much like an illicit minor in the third figure. It might also be treated as a fallacy of composition. It would seem as though the "intellectualists" ought to have a little respect for formal logic.

If you say that in the above case pragmatism is not new at all, but as old as science, I would quite agree with you. No one more than the pragmatist has disavowed any intention at originality. It is better to be true than original. But the amount of dust raised seems to indicate that an old, implicit scientific procedure was but vaguely understood. If the result of this paper should be to convince my readers that they are all "pragmatists," then we shall have "peace on earth, good will to men" once more, than which no more blissful consummation could be desired, unless it be strife.

PRAGMATIC REALISM

John Elof Boodin. "Pragmatic Realism." *Truth and Reality: An Introduction to the Theory of Knowledge* (New York: Macmillan, 1911), chap. 14, pp. 251–258.

In the following chapter I wish to discuss three points: the definition of realism; some objections against realism; and some consequences of pragmatic realism.

I

There has been a great deal of confusion in regard to terms in recent discussion. It may be well, therefore, to define, at the outset, what we mean by realism. A number of writers have called themselves realists and proposed to champion realism, when they are really indistinguishable from idealists. Here, at least, the Leibnizian law of indiscernible ought to hold. If the terms realism and idealism are retained at all, they ought to stand for different concepts. Leaving out all reference to the metaphysical stuff for the time being, realism means the reference to an object existing beyond the apperceptive unity of momentary individual consciousness, and that the object can make a difference to this consciousness so as to be known. The object, in other words, is dependent upon the cognitive moment, not for its existence, but for its significance. Idealism, on the other hand, would hold that there is strictly only one unity of consciousness and that existence is a function of being part of a significant cognitive system. Thought is so wedded to things that things cannot exist without being thought. This assumption on the part of idealism may be veiled under various terms, such as appearance and reality, the finite and the infinite, the incomplete purpose and the completely fulfilled purpose; but in the various forms of expression the assumption remains that all the facts are ultimately and really strung on one unity of thought.

Realism is an epistemological attitude and has to do with the relation of the cognitive meaning to its object. As regards stuff, it may be materialistic, spiritualistic, dualistic or pluralistic. As regards connection it may hold the mechanical interpretation concerning the relation of parts; or it may hold the teleological point of view; or partly one, partly the other, which is the position common-sense realism takes. As regards the numerical distinctness of the universe, it may be monistic, holding the universe to be one individual with

only apparent diversity in space and time; or it may be frankly pluralistic, holding to the numerical diversity and distinctness of individuals. As realism, therefore, is pledged to no brand of metaphysics, no odium need attach to it so far as metaphysics is concerned.

Realism, as I understand it, does not assume that there can exist isolated or independent individuals of such a kind as to make no difference to other individuals. No individual has any properties, chemical any more than psychological, by itself. Qualities are reactions or expectancies within determinate contexts. An isolated individual cannot even be zero, as zero must be part of a logical context at least. The hypothesis of independent reals is founded either on contradictory or on purely hypothetical conditions. Kant's things-in-themselves are instances of the latter kind. These cannot exist for experience or in relation to things as known. Yet they are supposed to be possible for an intuition entirely different from ours. Leibniz has recourse in the last analysis to an emanation theory and preëstablished harmony, which contradict his assumed independence. Cognitively independent his monads could not be in any case, since by implication they are aware of each other.

Realism does not deny that objects to be known must make a difference to reflective experience; that they are capable of being taken in a cognitive context. To deny this, within the universe of truth, would be self-contradictory. What realism insists is that objects can also exist and must exist in a context of their own, whether past or present – independent of the cognitive subject; that they can make differences within non-cognitive contexts, independent of the cognitive experience, of which the latter *a posteriori* must take account. Thus the wood in the grate burns, even though we are not taking account of it; the seed grows when we are asleep, through properties involved in its chemical context. Even our own meanings grow without our being reflectively aware of their change.

As our own cognitive meanings are necessarily finite, and any other type of knowing is necessarily hypothetical, it is difficult to see how any theory of knowledge can avoid being realistic. Absolute idealism, with its hypothetical unity; and mysticism, with its ineffable noetic intoxication, still must admit that the finite meaning, in striving for its completion, implies an object beyond its internal intent. To deny this is to fall into solipsism or to confuse one's self with the absolute. The complete absolute meaning cannot be said to depend for its existence upon our finite fragmentary insight. And it is with that finite intent that our problem of knowledge is concerned.

II

In order to clear the way for realism, we must get rid of some fundamental fallacies which permeate most of our past philosophic thought. One of these fallacies may be stated as the assumption that only like can make a difference

to like, or that cause and effect must be identical. This has been assumed as an axiom by idealism and materialism alike. For idealism and materialism are alike indiscriminative. Their method is dogmatic rather than critical. The only difference is in the stuff with which they start. Idealism, starting with meaning stuff, tries to express the whole universe in terms of this. Materialism, starting with mechanical stuff – stuff indifferent to meaning and value – must be consistent, or as consistent as it can, in expressing the universe in terms of this. Both buy simplicity at the expense of facts.

The problem is the old one of Empedocles: Can only like make a difference to like? "For it is with earth that we see Earth, and water with Water, by air we see bright Air, by fire destroying Fire. By love do we see Love, and Hate by grievous hate." Expressed in terms of modern idealism, from the side of individual consciousness, the problem would read: Can only experience make a difference to experience; can only thought make a difference to thought? The absolute idealist attempts this disjunction: The reality which we strive to know must either be part of one context with our own finite meaning, must be included within the completed purpose, the absolute experience, of which we are even now conscious as well as of our finitude and fragmentariness; or, on the other hand, the real object must be independent of our thought reference, must exist wholly outside our cognitive context, without being capable of making any difference to it. But complete independence is meaningless; therefore there must be one inclusive experience. To think an object is to think it as experienced, therefore it must be *experience*.

The issue at this point between the realist and the idealist is a two-fold one. The realist insists that there can be different universes of experience which can make a difference to each other; and also that what is non-reflective or non-meaning can make a difference to our reflective purposes, or *vice versa*. We can reflect upon a stone; that makes the stone experience *for us*. But does it also make the stone *as such* experience? It is as reasonable, at any rate, to say that only water can know water, and that therefore in order to know water we must have water in the eye or in the brain, as it is to say that in order to know the stone or to reflect upon the stone, the stone must be reflective. In either case our attitude is merely dogmatic. That objects in order to be known must be capable of being taken again, in the context of cognitive experience, is, of course, a truism. But that does not prove that they cannot exist without being known or that they must themselves be *experience* in order to be known.

Science has been forced to abandon the axiom that only like can act upon like. It is busy remaking its mechanical models in order to meet the complexity of its world. Chemical energy need not be the same as electrical or nervous energy, to make a difference to either. Chemical energy implies weight and mass, while electrical or nervous energy does not. The old metaphysical difficulty in regard to conscious and physical energy has given way to a question of fact. The question is not, *Can* they make a difference to each other? but,

Is there evidence of their making any difference to each other? A cup of coffee or a good beefsteak makes a difference to thinking. But that does not necessarily make them thought stuff. Whether cause and effect are identical, either in time or in kind, is something for empirical investigation to determine, and not to be settled a *priori*. Science presents strong evidence that they need be neither. The light rays may have traveled through space many years before they make the difference of light sensations in connection with our psychophysical organism; and that they make such differences does not prove that they are themselves sensations.

It is time that philosophy, too, were abandoning dogmatism in favor of facts. It is no longer a question of materialism or idealism; but we must use idealistic tools where we are dealing with idealistic stuff, and mechanical categories where the evidence for consciousness and value is lacking. We must learn to respect ends where there are ends; and to use as means those facts which have no meaning of their own. To fail thus to discriminate is to be a sentimentalist, on the one hand, or a bore, on the other. What we want is a grain of sanity, even the size of a mustard seed.

The merit of idealism, and for this we ought to give it due credit, is that it has shown that the universe must be differentiated with reference to our purposive attitudes. This is true whether the reality to be known is purposive or not. Where idealism has been strong is in interpreting institutional life. In order adequately to know another meaning, we must copy or share that meaning. This is true whenever our reality is thought stuff. Idealism, on the other hand, has always been weak in dealing with nature, and, therefore, in furnishing the proper setting for natural science. Idealism has striven to institutionalize nature or to reduce nature to reflective experience. In order to do this, it has been forced either to insist upon the phenomenality of nature, with Berkeley and Green, or to take the ground of Hegel, John Caird and Royce, that nature is essentially thought, social experience, the objectification of logical categories, though *an sich* and not *für sich*, *i.e.*, only as lived over by reflective experience. Hence nature becomes capable of system; it is essentially systematic. In thus hypostatizing the unity of apperception into an objective unity of nature, idealism has failed to discriminate. The stone and Hamlet are lumped together. But we cannot acknowledge or react on nature as experience on its own account, and therefore idealism breaks down. We make the *conceptual system* of nature, as social minds, to anticipate the future and to satisfy our needs. The *meaning* of the energy that satisfies, and of the transformations by which it satisfies, is furnished by our ideal context. That water satisfies thirst; that fire burns wood – these are extra-subjective energetic relations. But the why must be furnished by our scientific experience, partial and fragmentary though it is.

Materialism has been quite right in applying the mechanical categories to part of reality. The mechanical ideals will always find favor in natural science,

where the aim is not the understanding of an objective meaning, but *control* of nature for our purposes. Where the materialist shows his dogmatism is in applying categories which are convenient in dealing with the non-purposive structure of the world to institutional reality as well. In failing to make them work here, instead of calling into play new categories, he insists upon eliminating the refractory world of meaning and value, while the idealist, with his eye primarily on the world of social tissue or ideals, has insisted that the real is essentially the social or communicable. Each has failed to recognize how the other half lives.

Another dogmatic fallacy which has been committed by idealists, to smooth out the realistic discontinuities and ease the shock of actualities, is the play upon the implicit and explicit. I would not say that the category of the implicit has no legitimate use. Wherever we are dealing with a purposive whole of any kind, intellectual, ethical or esthetic, we not only can but must use the category of the implicit. The earlier part of the argument must imply or foreshadow the later within the logical unity. The earlier part of the dramatic plot must find its fulfillment in the later; the moral struggle points to an ideal. The abuse of the category of the implicit comes when we apply our purposes to infra-purposive realities. Because thinking as a process arises under certain structural conditions of complexity, this does not prove that earlier and simpler stages of development must be treated as degrees of thinking. There seem, on the contrary, to be qualitative leaps in the genetic series of experience, not reducible to the quantitative category of degrees. Thinking is a new fact in the series – furnishes a new context of significance. Again, because we systematize nature according to the presuppositions of the reflective moment, this does not imply a reflective unity in nature. Here again there seems to be a discontinuity, so far as meaning is concerned, which thought must acknowledge and cannot bridge, objectively, at any rate, by any implicit assumption as regards thought's own procedure.

Another current dogmatic fallacy is the assumption that because we *take* contents over in thinking them, therefore we *transmute* or make them over, if indeed we do not create them outright, in taking account of them. But the transmutation of the immediate or non-reflective has to do with its significance, not its content. The colors in the painting are the same that we have seen thousands of times, though here they are used to express a new meaning. The gold we think about has precisely the same qualities as the gold which was present as an object of immediate perception or esthetic admiration. It does not change its color or size because we reflect on it. It is the same object with the same qualities and relations, except that much of the existential has been omitted and the relation of cognitive significance has been superadded.

Another fallacy is the assumption that what is not stuff cannot be real. This assumption is very old. It is assumed by Parmenides when he dismisses non-being as unthinkable and unspeakable. It is assumed by Kant in his antimony

of space and time, when he maintains that the relation to nothing is no relation. Most philosophers have followed the leadership of these distinguished thinkers. But the assumption that zero is unthinkable and that the relation to nothing is no relation has been abandoned by mathematics for logical reasons. There is no more important relation in number than the relation to zero. The limiting concept of zero has also proved of great value in metaphysics as well as in mathematics. Take space for example: While space is no *thing*, yet as distance it is an important condition in the interaction of things.

III

Instead of the dogmatic method pursued by the old idealism and materialism alike, we must substitute the critical method. This method has been rechristened within recent years by C. S. Peirce and William James and called pragmatism. As I understand this method, it means, simply, to carry the scientific spirit into metaphysics. It means the willingness to acknowledge reality for what it is; what it is always meaning for us, what difference it makes to our reflective purposes. Instead of insisting upon identity of stuff, as dogmatism has always done, this method is discriminative. It enables us to break up the universe and to deal with it piecemeal, to recognize unity where there is unity and chaos where there is chaos, purpose where there is purpose and the absence of purpose where there is no evidence of purpose. The universe in each part or stage of development is what we must acknowledge it to be – not necessarily what we *do* acknowledge, but what we *must* acknowledge to live life successfully. This acknowledgment, moreover, is not a mere will to believe or volitional fiat, but, at least as knowledge becomes organized, a definite and forced acknowledgment. An unlimited will to believe as regards objective reality would be possible, if at all, only before we have organized knowledge, that is, if you could imagine knowledge starting in a conscious will-act. When we already have organized knowledge, if we choose to know, the possibilities become limited. In case of fully organized knowledge, the place of the indeterminate will-to-believe would be the will-not-to-think, that is, to commit intellectual suicide.

We can not state the truth attitude in merely subjective terms. The truth attitude must face outward. It must orient us to a context existing on its own account, whether past or present. In such orientation or such external meaning lies the significance of truth. The truth attitude cannot be characterized as merely doubt with a transition to a new equilibrium, and as ceasing with certainty. The truth attitude *may* at least involve the consciousness that we know that we know. To be sure, the nervousness of science leads us to repeat the experiment in order to make sure that we have made no mistake; but that does not alter the truth of our first finding, if the experiment proves correct.

Truth, as we have it, involves two things, – first, luminousness, or a peculiar satisfaction to the individual experience at the time, due to its felt consistency or fluent termination in its intended object. This is the positive truth value, whether formal or factual. The other factor involved in scientific truth is the feeling of tentativeness or openness to correction. This is a qualification or nervousness on the part of the truth attitude, either as a result of an actual feeling of discrepancy and fragmentariness as regards our present meaning; or it may be due to a more general feeling of instability based upon our finitude and the time character of our meanings. Such correction can only come through further experience, whether of the immediate or formal type. We cannot say that the value *consists* in the future consequences or leadings. These obviously have no value until they come. Further experience furnishes the possibility of correction of our truth values and so of producing new values. I say *possibility* of correction because repeating the experiment, while it relieves our nervousness, does not necessarily produce a new truth. The truth meaning must first be stated in schematic terms on the basis of the data as we have them and then tried out in terms of consequences. Such consequences must be in part present to us as a result of past experience. We do not formulate theories *in vacuo*. If the truth value lay merely in the future consequences or leadings, there could be no such thing as truth value. Truth must face backward in order to face forward. It is Janus faced.

We may lay it down, then, that the real must be known through our purposive attitudes or conceptual construction. Real objects are never constituted by mere sense perception. They are not compounds of sensations. Sensations are our awareness of the going on of certain physiological changes, whether connected with an extra-organic world or not. They cannot be said, therefore, to constitute things. These presuppose selective purpose. They can only become objects for a self-realizing will. The real is the intelligible or noumenal, not the mere immediate; and by the noumenal I mean what we must meet, what reality must be taken as in our procedure, as opposed to our sensations. It is through conative purpose that knowledge of the character of our world becomes possible. The immediate, however, must furnish the evidence; in the language of James it puts us next to the real object. It establishes energetic continuity with the intended context of reality.

Empiricism is at best a halfway house. We cannot say that the real is merely what *is* perceived or what *makes* an immediate difference to our conscious purposes, whether in the way of value or of fact. We must at least say that the real is what *can* be perceived, unless we bring in some *deus ex machina* or supernatural storehouse of percepts, as Berkeley does. Surely the empirical idealist of to-day would not say that the increased powers of the telescope or microscope create the facts. Nor can the *uniformity* of our expectancies be credited to our individual perception; and hence from the perceptualist point of view, it requires another *deus ex machina*. To say that

uniformity or stability is a social fact does not explain the fact, but presupposes an extra-social constitution, a constitution binding upon all of us. Not only perception, but *possible* perception must be invoked to complete the empirical idealist's reality; and "possible" itself is not a category of perception.

As the old idealist and the old realist alike assumed the qualitative identity of cause and effect, it became necessary to think of subjective states as copies of external qualities. Naïve realism and idealism alike assume this copy-relation of the subjective on one hand and the real qualities on the other. In modified realism, the primary qualities at least must be copied. For the empirical idealism of to-day the problem still remains as to whether the perceptions and the objective qualities are the same. Unless the idealist becomes a solipsist he must show that his subjective copies are adequate to a world as existent. This difficulty would vanish, once we abandoned the dogmatic and unintelligible duplication of qualities, as though qualities could exist passively by themselves. Qualities are energies. They are what objects must be taken as in determinate contexts. To ask what perceptual qualities are, when they are not perceived, becomes in that case as superfluous as it is meaningless. Processes, of which we are not conscious, have no perceptual qualities, unless, under certain other conditions, they can make perceptual differences to beings organized as we are. To speak of archetypal qualities is merely duplicating this moment of perception – to take what exists in a context as an abstract idea. If these non-conscious reals act upon other non-conscious reals, we have not perceptual differences, but chemical or physical changes. These must be interpolated by us in order to make continuous our perceptual scheme. We saw the wood burning in the grate: in our absence the fire has gone out and the wood has turned to ashes. To piece together this discontinuity in our perceptions, we must assume certain differences or changes which cannot themselves be expressed as perceptions. And thus we come to realize that while we must take some qualities of things as existing as part of our perceptual context, we must also take other qualities as existing independent of perception in their own dynamic thing-contexts, which we can read off *a posteriori* and predict under determinate conditions.

Perceptual qualities, therefore, are not the only qualities. Even granting a being who should have perceptual differences for all the changes going on, minute or great, and without breach of continuity, he would not have a complete account of reality. The real individual cannot be exhausted as a compound of perceptual qualities. He must be acknowledged as something more than the sum total of his sense appearances, past, present and future. If sensations alone constituted reality, then the more sensations the more reality. Take Helen Keller's reality, for example, on this supposition. For convenience, I will use Professor Titchener's estimate of the number and kinds of sensations, leaving aside the question here as to whether all sensations can be taken as sense qualities. According to him, sight furnishes us 32,820

different sensations, hearing 11,600, making a total of 44,420. As Helen Keller possesses neither the sense of sight nor that of hearing, her reality would be to our reality as 15 is to 44,435. But Helen Keller seems to be able to enter into communion with human beings all over the world, to share their purposes, to sympathize with them and help them better than most human beings with the use of all their senses.

The reason the position that reality is the sum of its perceptions has seemed so plausible lies partly in the fallacious use of the method of agreement, partly in the confusion between the *causa cognoscendi* and the *causa essendi*. The perceptual qualities do exist; and it is through them we become immediately conscious of an external world. Objects are what they are perceived as, but indefinitely more. We must not forget that there are other contexts, such as the multitudinous thing-contexts and the contexts of our will attitudes. These may be practically more significant for determining the reality of a thing than our sensations – not all of which can be treated as sense qualities. It may be of more practical significance for the nature of water that it satisfies thirst than that it gives us a number of contact reactions. When we come to deal with a human being, a friend of ours, the inadequacy of mere perceptual qualities becomes even more evident. He is not to be taken merely as his height, nor his color, nor his softness, nor his hardness, nor even the sum total of all the perceptions we can get. He is primarily what we must acknowledge, what fulfills a unique purpose on the part of our wills, and, as opposed to the gold or the stone, a reality with an inner meaning which we can to some extent copy.

We have seen that experience becomes truth only through conceptual construction or purposive will attitudes. Percepts only become cognitively significant as *termini* of ideal construction, as verification stuff. No wonder that the perceptualists have not been able to discover non-being dimensions, since these could not be perceived, but discovered only through the most subtle conceptual tools, according to the real difference which they make to our purposive striving. We have already indicated that because reality can only be known through conceptual construction, that does not mean that reality must be conceptual. Reality is, however, knowable only in so far as it is conceptualized. In recognizing that reality could not be treated altogether as purpose, moral or intellectual, Kant showed a keenness far exceeding that of his critics.

Since perceptual qualities are the felt continuities or functional connections of energetic centers, when a conscious agent is part of the complex, there can be no sense in speaking of these qualities as either acting upon the will or parallel to the world of will acts. The perceptual qualities do not exist independent of the concrete situation, so that they could act upon it. They are what the object must be taken as, or known as, in the special psycho-physical context. They preëxist only potentially, *i.e.*, as what the object *can* be taken

as in the determinate context. They are, however, only one type of transeunt connections or energetic continuities. These energetic continuities may be intersubjective relations, and in that case communication and conceptual understanding are possible. They may be relations to centers below the reflective level. In that case knowledge becomes instrumental – a reweaving of a non-meaning context into the unity of our purposes.

Equipped with our subjective purposes, or conceptual tools, we can confront the larger world. In the course of conscious experience, as we strive to realize our tendencies, formal or practical, the world beyond us becomes differentiated and labeled according to our success or failure. But the real objects are not constituted by our differentiation, except when we make our realities outright, as in the case of artistic creation. The meaning for us is, indeed, created in the course of experience, but not the objects which we mean. Else science were impossible. The real objects must be acknowledged or met, whether they are to be understood or to be controlled.

The world of real objects may be differentiated into two general divisions, the world of being or stuff, on the one hand, and the world of non-being or non-stuff, on the other. By the former I understand various types of expectancy or uniformity, which we can have in regard to our perceptual world. These types of uniformity, again, can be graded into two main divisions, namely, those which we can acknowledge metaphysically as purposive in their own right and those we must acknowledge as existing and must meet, but which have no inwardness or value on their own account. The former we must learn to understand and appreciate, the latter to anticipate and control. The former constitute the realm of idealism, the latter of materialism. As regards the stuff character of reality, this theory is frankly pluralistic, acknowledging different kinds and grades of energetic centers according to the differences they make to our reflective purposes.

But we must also take account of the non-stuff dimensions of reality. These differ from the stuff types in that they are not perceptually continuous with our psycho-physical organism. They cannot appear as immediate phenomena, but still must be acknowledged for the realization of our purposes. Thus we must acknowledge the transformation of our values, the instability of our meanings. *Time* creeps into our equations and makes revision necessary. New values can only be had by waiting. Again, *space*, as distance, abstracting from the content of space, conditions our intersubjective relations, as well as our relations to non-purposive beings. It makes possible externality of energetic centers and free mobility. Further, the relativity of our meanings and ideals makes necessary the assumption of an absolute *direction*, a normative limit, to measure the validity of our finite standards. Lastly, we find it convenient to abstract the fact of *consciousness* from the psychic contents and the conative attitudes. While our awareness is intermittent, the conative attitudes and purposes may be comparatively

constant. These non-stuff dimensions must be regarded as real as the will centers which they condition. They are more knowable than the world of stuff, because their characters are few and simple, whereas the varieties and contexts of stuff are almost infinite. Thus, by means of our conceptual tools, we are able to discover not only various kinds of stuff, but we are able to discover dimensions of reality of ultimate importance, where microscopes and telescopes cannot penetrate – realities which eye hath not seen nor ear heard, nor ever will see or hear, more subtle than ether or radium.

PRAGMATIC ENERGISM

John Elof Boodin. "Pragmatic Energism." *A Realistic Universe: An Introduction to Metaphysics* (New York: Macmillan, 1916), chap. 3, pp. 33–61.

The Nature of Energy

Through a chronic tendency of the human mind, due to the stereotyping effect of language, philosophers have sought for energy as a thing-in-itself. It has long been maintained that we can know only the effects of energy, and the conclusion has been drawn that energy itself is inscrutable and unknowable. If effects or changes are merely external relations, they will indeed show us nothing about things. But it must be clear that such an agnosticism is of our own making. Since the fundamental characteristic of energy is activity, it would seem that the saner attitude is that of common sense and science, both of which estimate energy by what it does. What we know about our world in our experience is meager enough, but we have at least a right to assume that our fragmentary evidence is real so far as it goes. And if energy reveals itself in certain physical and psychological changes, these, we must assume, indicate the nature of energy. We must hold to the pragmatic postulate that energy is what it does. Any other assumption is suicidal at the outset.

Others have insisted that we have immediate and intuitive evidence of the nature of energy in our sensations of strain, our feeling of effort. Now this is true, no doubt, to the extent that, if we were not ourselves active beings, we should not be conscious of energy in nature. The fact is that we should not be conscious at all. Psychological analysis shows that the feeling of effort consists in certain kinaesthetic sensations – sensations of muscular tension about the forehead and in the throat, of labored breathing, etc., when we are baffled by a problem. But these sensations are not mental activity. They are reflexes merely, – symptoms of a somewhat unorganized or obstructed stage of activity. They are not concomitant to all our activity. When the particular activity becomes organized and proceeds fluently and easily, the sensations of strain disappear. But the activity does not disappear; on the contrary it is now most efficient.

Science has followed the pragmatic method and insisted that energy must be known by work done and the sort of work that is done. It is true that in the minds of scientists there have lingered reminiscences of an antiquated metaphysics, of an energy-in-itself, of occult "forces," and "latent" energy.

But such misconceptions have had no effect on the empirical results of science. These have to do with predictions of behavior under definite conditions. And by behavior science does not mean merely a sequence of perceptions. The assumption that these constitute the whole story is a metaphysical interpretation of science. Of course we must know reality through our perceptions, *i.e.* we must become aware of its changes. But science does not assume, as phenomenalism does, either that we are dealing *only* with perceptions or that our perceptions of things are "faked" manifestations of an energy in itself. Our perceptual system may inform us of what energy does in systems outside of the cognitive relation. Our seeing the gunpowder, and the spark applied to it, and the explosion with its results, informs us of what is happening in our environment. It is not our perception of the explosion which makes the explosion occur; the work done by the energies involved must be taken account of in their own context. In other words, science is dealing with real activities, as revealed in various contexts, including our perceptual context. Whether again we measure energy in foot pounds, the work necessary to lift a pound a foot in a second, or in dynes, the work necessary to lift a gram one centimeter in a second, is of course purely a matter of practical convenience, and has no philosophic interest.

Work and inertia are merely two different points of view, due to the special interest for the time being. In speaking of work we emphasize the going on of activity in connection with a series or direction which we have selected. In speaking of inertia or mass, we emphasize energy which must be balanced, overcome, or withdrawn. To start a body moving we must overcome its inertia or its energy of position. Again, we cannot annihilate the energy of a moving body. According to Newton's first law, if a certain initial energy is communicated to a body from a definite base, it will move uniformly in a straight line unless interfered with by other energies. Here energy must be withdrawn or transformed in order for the body to stop moving. To eliminate interference, again, means the withdrawal of energy. In our practical social relations, we use inertia in a similar sense: it means energy which must be overcome or withdrawn. We must overcome people's opposition, scruples, or habits. We may be reformers trying to overcome people's prejudices, or we may be confidence men trying to withdraw people's caution. Work and inertia are pragmatic distinctions depending on our special interests in dealing with our world. They hold for all energies, whether it be material masses in space, or electric currents, or social interactions. We can see, then, that inertia is a universal characteristic of energy.

The simplest unit of reality is an energy system. Things do not have properties in themselves; they possess properties only within a system, and such properties vary with the conditions which determine the system. That properties exist in the abstract is one of the last superstitions of the old metaphysics. Take weight, for example, the most important property of

mechanical science. Does weight exist in things by themselves? We know that the weight of a body varies at different points of the surface of the earth. It is a function, though we do not know how, of the attraction of the earth. According to Newton's law, bodies attract each other in proportion to the mass, and inversely as the square of the distance. For very large distances, we know now that gravitation becomes negligible; and of course for infinite distance it becomes zero. A body at an infinite distance from other bodies would have no weight, which amounts practically to the same as saying that bodies by themselves would have no weight. If you say that such bodies have potential weight, that is the same as saying that they do have weight when they exist in connection with a certain finite system. The same could be shown for other qualities. Extension is a property things have for us in a certain perceptual energy system. This implies, beside certain external energies, a certain stimulation of the cells of our end-organs, and of our cerebrum. The number of physiological processes stimulated seems an important condition, though the sequence of stimulations must also be taken into account. In any case, extension as perceived is real only in an energy system, and varies with this. And the same is true of the extension of things with reference to each other. It varies with motion, temperature, and pressure. In so far as we apply size and weight to corpuscles moving with the velocity of light, both properties depend largely, if not altogether, on motion. Properties have no meaning for science, except as energy determinations, characteristics within energy systems. And this is as true for what we have been accustomed to call primary qualities as for the so-called secondary qualities. Science knows nothing about absolute properties.

The concept of energy as a universal generalization is a thin concept. But any predicate of the whole of reality must be thin. How convenient it would be if we could condense reality altogether into one formula, requiring no supplementary definitions, – matter, spirit, electricity, anything that could be substituted for the pluralistic variety of our world. But leaving *a priori* and sentimental preferences out, we must find what experience warrants us in saying in general about this variety. And the predicate of energy is at least more fruitful than the medieval, lexicographical predicate of being. It furnishes a methodological postulate without which science is impossible, and a program which can be filled out by scientific research. This methodological advantage of the concept of energy is stated clearly in Professor More's summary of Rankine, the founder of the science of energetics: "Instead of supposing the various physical phenomena to be constituted, in an occult way, of modifications of motion and force, he attempts to frame laws which shall embrace the properties common to any one class. He finds energy, or the capacity to effect changes, to be the common characteristic of the various states of matter to which the several branches of physics relate. If we then frame general laws regarding energy, we shall be able to apply them with

appropriate changes to every branch of physics. In all cases we have a certain quantity of energy active in a definite manner. Our aim should be to find by experiment the properties of any such manifestation, and to combine all common properties by general mathematical laws."[1] This principle of Rankine can be extended, we believe, to the whole field of reality, including organic and psychic changes, however difficult it may be in the latter cases to formulate our results in exact mathematical terms. Wherever you have knowable entities, whatever their stuff may be, there you must have equivalencies in the way of predictable differences. Only in so far are they knowable. We must know reality by the differences which it makes to our practical conduct.

The Postulates of Energy Systems

Our energy systems are cross sections of reality in the service of our special purposes. They are pragmatic, but that does not mean that they are unreal. They are real just insofar as they are based upon genuine characteristics. In analyzing any such system there are certain general postulates holding for all systems: there must be certain variables, there must be the form or organizing relation of the system, and there must be recurrence. Recurrence is the pragmatic equivalent of what an older metaphysics spoke of as substance. We must now try to illustrate the working of these postulates in some typical energy systems.

In a mechanical system, such as that of ordinary kinetic energy, we have three independent variables: gravitation mass, space units, and temporal units. For purposes of social description, these variables must be standardized. We ascertain the gravitation mass at a certain location on the earth's surface, Paris for example. We standardize our space units in terms of some common measure, kept at a certain constant temperature, whether it be the steel yard in London or the meter in Paris. We standardize our temporal units in terms of sidereal time, and our clocks are so regulated. These units are constant for practical purposes, but they are at best pragmatic measures. The mass of the earth, sidereal time, and our conventional space measures are all undergoing variations, but so long as they serve our common purposes, we can ignore such variations. If all bodies in space varied correspondingly, owing to motion or electromagnetic action, we should not be able to detect it. But since the quantities measured and the measure would vary together, we should not be practically affected by this universal relativity. Furthermore, our simple mechanical system has form. It is uniquely determined by the three factors mentioned, *viz.* gravitation, space, and time units. It is statable in terms of a

[1] *Hibbert Journal*, July, 1909, p. 785. The views of Rankine are to be found in a memoir read before the Philosophical Society of Glasgow in 1855.

simple formula: ?MV^2, where M stands for mass, and V for velocity. And, finally, while we live in a world of constant flux, and try to steer our behavior in such a flux, the system in question repeats itself in such a way that we can use the same formula again and again under the stated conditions.

In a more complex material system, such as a chemical system, we can analyze the system into the same elementary postulates. If we wish to explain the compound, water, for example, we must take account of the variables – the properties of hydrogen and oxygen, and of temperature. We state the organizing relation asH_2O, the combining proportion of hydrogen and oxygen. And once we have standardized the factors, we are able to repeat the formula so long as the conditions on our earth remain fairly uniform, *i.e.* for all practical purposes.

In analyzing electrical systems, we do not seem to be able to use gravitation mass as one of our variables. It seems to be empirically true that charging a metal bar with any amount of electricity does not alter its weight. But science has found other variables no less clear and definite. We know electrical energy, as we do mechanical, by the work it does. "The presence of an electric current is recognized by three qualities or powers: (1) by the production of a magnetic field, (2) in the case of conduction currents, by the production of heat in the conductor, and (3) if the conductor is an electrolyte and the current unidirectional, by the occurrence of chemical decomposition in it. An electric current may also be regarded as the result of a movement of electricity across each section of the current, and is then measured by the quantity conveyed per unit of time."[2]

In electrical energy, as in mechanical, we are able to apply our three postulates. We have certain variables, a certain form which is mathematically statable, and we have recurrence. "A current flows in a circuit by virtue of an electromotive force, and the numerical relation between the current and the electromotive force is determined by three qualities of the circuit called respectively, its resistance, inductance, and capacity."[3] In the case of continuous, unidirectional conduction currents, the resistance of the circuit is the only one of the above mentioned qualities of which we need to take account. The relation of electric motion to this is formulated as Ohm's law, "which states that the numerical value of the current is obtained as the quotient of the electromotive force by a certain constant of the circuit called its resistance, which is a function of the geometrical form of the circuit, of its nature, *i.e.* material, and of its temperature, but is independent of the electromotive force or current."[4] "We may otherwise define the resistance of a

[2] Article, "Electrokinetics," *Encyclopaedia Britannica*, 11th ed., Vol. IX, p. 211.

[3] *Ibid.* p. 211.

[4] *Ibid.*

circuit by saying that it is that physical quality of it in virtue of which energy is dissipated as heat in the circuit when energy flows through it."[5] When we deal with alternating or periodic currents we have to take into account inductance as well as resistance. Inductance "may be defined as that quality in virtue of which energy is stored up in connection with the circuit in a magnetic form. It can be experimentally shown that a current cannot be created instantaneously in a circuit by any finite electromotive force, and that when once created, it cannot be annihilated instantaneously. The circuit possesses a quality analogous to the inertia of matter. If a current, *i*, is flowing in a circuit at any moment, the energy stored in connection with the circuit is measured by ?Li^2, where L, the inductance of the current, is related to the current in the same manner as the quantity called the *mass* of a body is related to the velocity in the expression for the ordinary kinetic energy, *viz.* ?MV^2. The rate at which this conserved energy varies with the current is called the 'electrokinetic momentum' of this circuit (= Li). Physically interpreted this quantity signifies the number of lines of magnetic flux due to the current itself which are self-linked with its own circuit."[6] In electrical energy, therefore, as in ordinary mechanical energy, we can define the variables involved in its activity, we can state its organizing relation in terms of simple mathematical formulae, and we can predict the future for practical purposes under the stated conditions.

If, again, we take an organic system, we find that we can deal with this on the basis of the same postulates. Here too we have our variables, our organizing relation, and recurrence. Life, complex as it is, is after all, a chemical compound. "Protoplasm, the living material, contains only a few elements, all of which are extremely common, and none of which is peculiar to it. These elements, however, form compounds characteristic of living substance and for the most part peculiar to it." Of such elements, the most significant is proteid, consisting of carbon, hydrogen, oxygen, nitrogen, and sulphur. Among other elements are such organic compounds as fats, carbohydrates, and various inorganic substances such as salts and water. "We attain, therefore, our first generalized description of life as the property, or peculiar quality of a substance composed of none but the more common elements, but of these elements grouped in various ways to form compounds ranging from proteid, the most complex of known substances, to the simplest salts. The living substance, moreover, has its mixture of elaborate and simple compounds associated in a fashion that is peculiar.... Life is not a sum of the qualities of the chemical elements contained in protoplasm, but a function first of the peculiar architecture of the mixture, and then of the higher complexity

[5] *Ibid*. p. 212.

[6] *Ibid*.

of the compounds contained in the mixture. The qualities of water are no sum of the qualities of hydrogen and oxygen, and still less can we expect to explain the qualities of life without regard to the immense complexity of the living substance."[7] It is true that the synthetic chemist has not been able to account for the origin of protoplasm by artificial manufacture from the known ingredients, but this, he feels, is due to the fact that he has not yet discovered the unique conditions of temperature, pressure, etc. which were present at the geologic origin of life. In any case his ignorance would not be helped by assuming another element such as vital impulse. Vitalism seems to be laboring under the confusion of trying to account for the unique organizing relation as a discrete element in the compound, which is like introducing a water impulse to account for the unique properties of water.

What impresses us about such an energy system as life is not so much the variables of composition, concentration, temperature, etc., as the architecture or organization. What baffles us when we try to characterize life is that the elementary properties we may enumerate may be found singly in other and simpler systems. Just as we cannot point out a unique element in the composition of life, so it is difficult to point out a unique property. Does living matter grow by intussusception as opposed to superficial addition? So do inorganic liquids, as when a soluble substance is added. Is living matter irritable? It is easy to find inorganic matter which is sensitive to specific stimulation. The camera film is far more sensitive than our eye; the resonator than the ear, etc. As regards instability, if we use Spencer's formula that "life is the continuous adjustment of internal relations to external relations," we can parallel the readjustments in the case of life with those of inorganic nature. In either case, the action of the stimulus is complicated by the organization of the system and its potential energy. As regards mobility, so far as that is characteristic of life, the Brownian movement is the very image of perpetual mobility, and was first mistaken for a living compound. So we might parallel simple reproduction by "the breaking up of a drop of mercury into a number of droplets." Cumulative disposition and differential action on the basis of it can be paralleled in the inorganic world. Nor are discriminative selection and reaction upon a type peculiarities of the organic world. And, finally, the inorganic world acts in accordance with the principles of logic and mathematics, even though it may not be conscious of so doing. If you take the whole range of organic action, therefore, you could doubtless parallel the various properties and functions in the inorganic world. In the large, too, the latter reveals such selective adaptation and compensation in its moving equilibrium as would require an "omniscient demon" to establish. The uniqueness of life lies in the fact, long ago pointed out by Fechner, that life in its evolution brings together

[7] The quotations are from Dr. P. C. Mitchell's article, "Life," in *Encyclopaedia Britannica*, 11th ed.

and correlates, into one unique ensemble, a vast array of properties, which are scattered in nature. This ensemble has unique properties of its own, new ways of storing potential energy, and new modes of behavior. No theory of the origin of life or its relation to antecedent evolutionary stages can affect the uniqueness of the system itself. Nor must we regard its spontaneous or uncertain character, for our limited powers of prediction, as a peculiar merit. For, in the first place, this is due largely to our ignorance; in the second place, we value conduct because it is dependable as well as because it is novel. We prefer people who are invariably truthful, honest, just, and kind to those who are liable to do anything whatsoever.

If we, finally, take up the most complex type of energetic system with which we are familiar, *viz.* that of social interactions, we must here too apply the same postulates. We must discover the variables, the organizing relation, and the type of recurrence which we can predicate. We can abstract, for the purpose, from the material conditions, such as geographical configuration, temperature, water supply, character of the soil, etc., as well as from the organic conditions which form the background of the race, and deal with a social system as a closed system, as we have done in the other types. We may find analogies from the more elementary systems useful here. Sir Joseph Larmor, in speaking of a material system, says: "The amount of energy, defined in this sense by convertibility with mechanical work, which is contained in a material system, must be a function of its physical state and chemical constitution and its temperature."[8] Translating these categories into terms of society, we may say that the variables in a social system are the group conditions in the way of greater or less condensation of numbers, the mental constitution of the factors involved, and the common emotional excitement. Durkheim has oversimplified the problem when he tries to account for society in terms of volume (or number) and density, the definition of material mass. These have indeed their appropriateness. We find that volume is a variable involved in social conduct. The volume of suggestion makes it more effective. The number engaged in the action affects the conduct of the participants in an altered sense of responsibility and in the checks and releases that obtain. We find, too, that density or proximity has its corresponding effect. It gives a peculiar reality and vividness to the relation, which is particularly marked in crowd action. But these variables, if used in any limited sense, are not the only ones. To understand the psychic state or inertia, we must take account of the peculiar equilibrium at the time, within the group in which we wish to produce effects. This may be a static equilibrium in the way of habits and traditions, or a moving equilibrium in the way of certain tendencies which the group is striving to realize. In each case the sort of equilibrium that exists conditions our action. Timeliness of suggestion is important if we would accomplish

[8] Article on "Energetics," *Encyclopaedia Britannica*, 11th ed.

results. In an equilibrium moving in the opposite direction from our intent, we may find that hitting it laterally, or by indirect suggestion, encounters less inertia than hitting it head on. Again, as regards constitution, we find that we must take account of the individual characteristics of the components in the way of inherited and derived tendencies. The mental constitution conditions the type of action which we can expect. We must know our people, their race traits of instinct and temperament, and their psychological tendencies of needs, ambitions, and aversions. This is quite as necessary as knowing the elements which enter into the chemical compound. In either case, if we fail to take account of the reactive properties of our elements, we may find ourselves unwilling participants in an explosion. We must try to discover, too, the amount of emotional excitement which is necessary for the specific reaction to take place. Social compounds have their boiling point and freezing point, their point of solvency and crystallization, as truly as chemical elements. We must find what degree of affirmation or passion will precipitate the special type of reaction. As in the case of dynamite, the instability of the structure may make the effect out of all proportion to the releasing stimulus. Witness the present war of the European nations.

To understand a social kinetic system we must take account of the organizing relation, as well as the variables of its constitution. We must find the thought form, the ruling passion, the dominant purpose, which makes the tendencies converge in one direction, be the interaction between individuals within the group, between the individual and the group or between groups. Sometimes lust for power, sometimes love of wealth, sometimes self-preservation, sometimes racial prejudice, sometimes loyalty to truth and right form the organizing bond. But always there is a striving for unity and simplification, for a new equilibrium, and this gives direction to the struggling motives. And as in physical systems, the movement is direct or in a straight line, except as there are interferences to overcome or go around, so in the social system. In the end, ideal unities are the only ones which can succeed in giving an adequate and durable direction to the various claims. Unified action must be reasonable action.

In social systems, as in simpler systems, there must be such recurrence of traits and situations as makes prediction possible. The difference lies in the enormous complexity of the social situation. By means of statistics, we can, to a certain extent, eke out individual observation; and in regard to some types of reactions such as marriages, births, suicides, etc., our curves are fairly constant; or, at any rate, the deviations are clear. For understanding the deeper motives and effects of human conduct, we need historic perspective. But here, as in the simpler systems, the facts have their own perspective of which we must take account, relative though our interpretation must necessarily be, in virtue of the fact that history is potentially infinite and that interpretation is of the very essence of the creative human process.

In analyzing energy systems we have selected our illustrations from the kinetic state of energy. This is due partly to the fact that we found this procedure simpler, but more to the fact that this state of energy, is more significant for metaphysical purposes. The potential state, that of position or configuration, derives its significance from the moving state. By potential, we mean what energy *can* do when certain conditions are supplied which are different from those obtaining. Thus, to pass from energy of position to the kinetic state, there must, somehow, be unequal distribution of energy. In the case of falling bodies, we have unequal distribution of gravitational energy. Thermodynamics is built on the unequal distribution of heat. In the case of electrical energy, "if any cause operates to add or remove electrons at one point, there is an immediate diffusion of electrons to reëstablish equilibrium, and this electronic movement constitutes an electric current. This hypothesis explains the reason for the identity between the laws of diffusion of matter, of heat, and of electricity. Electromotive force is then any cause making, or tending to make, an inequality of electronic density in conductors, and may arise from differences in temperature, *i.e.* thermo-electromotive force, or from chemical action when part of the circuit is an electrolytic conductor, or from the movement of lines of electromagnetic force across the conductor."[9] In the case of social systems, it would be a case of the unequal distribution of emotional-volitional excitement.

In the potential state, energy is just as real as in the kinetic state, but is balanced or in equilibrium for the time being. In the case of a building supported on pillars, the energy of the pillars balances, for the time being, the gravitational energy. In the case of human actions, certain tendencies to action are balanced for the time being by inhibitions. A man would steal, but he is afraid of the police. In either case, when the balancing energy is withdrawn, we have an unequal distribution, and the persistent tendency becomes kinetic energy.

The term potential, however, is sometimes used when we contrast expectancies under one set of kinetic conditions with those under another set. Certain electric vibrations can become sensations of light to us when they act upon a photochemic retina; and certain air vibrations can become sensations of sound when they strike our ear and are transmitted to our cortical centers. Here the contrast is not between energy of configuration and energy of motion, but between what happens in the case of different reagents. In any case, the properties which are observed in certain contexts cannot be said to preexist independent of the contexts as was supposed by Anaxagoras, for example. According to him, the fruit of Demeter which we eat, and the water which we drink must contain the germs of blood and tissue and bone and hair which they serve to build up. The reason that things can produce

[9] Article on "Electrokinetics," *Encyclopaedia Britannica*, 11th ed.

such different results in different combinations is that everything contains a portion of everything. It is only the proportion of the properties which varies, and which determines the character of the particular thing. If pain is present in stimuli of a great intensity, then it must be a latent property at any intensity. But potential is not a category of the actual world, but of our social expectancy. The chicken is not present in the fresh egg at all. It would be nauseating to think so. Knowing that certain properties appear in certain energy systems, we can predict that they will recur when the conditions are repeated, but they are only real within the system.

Potential energy, therefore, is not to be regarded as a distinct type, to be set over against such types as material and electrical systems. It is rather a set of expectancies which we may have in regard to any type when we contrast one condition with other conditions. We may contrast the condition of balance or equilibrium with work done when the special type of energy exists in a kinetic state; or we may contrast the work done under one set of kinetic conditions with that done under another set. Nature obviously does not know the word potential. It is a contrast which is contributed by our mind. In reality each reactive relation is uniquely determined, – in the case of material systems, by such characteristics as the physical state, chemical composition, and temperature, by geometrical pattern and direction, by cumulative numerical values, and by distance. Potential is not a characteristic which figures in the determinations of a system. The tendency to read our expectancies into reality as though they existed prior to and independent of the dynamic situation is only another instance of the pathetic fallacy.

Some Empirical Laws of Energy

We have dealt so far with different types of energy systems and the factors which determine such systems. While each type of system must be taken as unique and its specific characteristics observed, there are some characteristics which seem to hold for all systems of energy. Beside the general postulates of variable, form, and recurrence which hold for all systems, there are certain empirical postulates which pertain to energy systems in particular. These general characteristics are sometimes called laws, though this is somewhat of a misnomer since they have only been verified for some limited systems. One of these is the law of conservation of energy and closely associated with this is the conservation of mass. The law of conservation of energy has definite meaning when we deal with special energy systems. In a material system, for example, it signifies that when a certain amount of energy disappears as motion, it reappears as heat; and the quantity of heat is equivalent to the lost motion, though from the point of view of available energy it is only in part convertible into motion. It is equally easy to show the meaning of the law in the case of an electrical system of energy. Energy which disappears as

electricity is found to reappear in the equivalencies of mechanical motion, chemical decomposition, or heat. In organic and social systems it is difficult to ascertain exact equivalencies in the complexity of changes involved. But here, too, we can in part, at any rate, note such equivalencies. In fact it was in connection with the potentials of foodstuffs in their relation to physiological activity, that Mayer first suggested the law, which was afterwards tested for material and electrical energies by Joule. It is clear that in organic and mental work there is a relation between nourishment and work done; there is also an equivalent in the way of heat as energy is used up. The heat of the skull, in the case of mental activity, is found to increase, and can be measured, though that of course is only one of the equivalents of mental work. Here as in mechanical energy, we must take account of the going on of the impulse itself and its effects in kind, which it would not seem possible to measure in an exact way. When you try to state the law of conservation of energy as true of all systems, Poincaré is quite right that it is necessarily vague. It signifies that there is some sort of constancy, that there are equivalencies, but it furnishes no definite content. Even so, however, it has more meaning than the old barren formula of identity in difference.

The law of conservation of mass or inertia is similarly empirical. It has been verified for some of the simpler systems of energy. Gravitational mass can be taken as practically constant at a certain point of the earth's surface. In the case of electrical mass we can measure the inertia of the current or electromagnetic field. In the more complex forms of energy, such as the organic and social systems, we are equally aware of the reality of inertia, and must deal with it, though we have no exact way of measuring it. We know, in any case, that inertia varies with motion. A moving body presents a different inertia from a body at rest. In the case of high velocities, approximating the velocity of light, there is a sudden increase of mass. Mass also varies with direction. A body in motion presents greater inertia to a body moving in the opposite direction than to a lateral impulse. This is equally true of the inertia of material bodies, of electric currents, and of social inertia. The constancy of mass in any case is a pragmatic affair.

Another characteristic, which seems to be practically general so far as our observation is able to go, has been called the law of degradation of energy. There is a tendency for energy to move from a higher to a lower potential. Since activity depends upon an unequal distribution of potentials, there would seem to be a tendency for the available energy to decrease, and for the universe to run down. This is particularly noticeable in connection with the constant tendency for a certain amount of energy to be dissipated as heat which can only in part be made available; but it holds wherever there are uncompensated expenditures of energy. This law does not contradict the law of conservation of energy since the sum total of energy would still remain constant, even if all available energy were diffused into random molecular

motions, such as we observe energy seems to be inevitable in the Brownian movement. While the degradation of energy seems to be inevitable, from the point of view of our limited survey and control, it cannot be regarded as an ultimate law of the universe. The Greeks with inferior tools, but a superior imagination, realized this. In the words of Empedodes: "For if they (the elements) have been passing away continually, they would not be now."[10] Maxwell showed that an omniscient demon, by sorting all the greater velocities on one side of an imaginary partition, and all the lesser velocities on the other side, could create new available energy. "This shows that the principle of the dissipation of energy has control over the actions of those agents only, whose faculties are too gross to enable them to grapple individually with the minute portions of matter which are the seat of energy."[11] If the universe is infinite in time, there must be some compensating agency corresponding to Maxwell's omniscient demon which keeps the universe wound up. It remains true, nevertheless, that for our practical purposes energy systems are in part, at any rate, irreversible.

Any postulate, which is based on a one way process, – such as the law of equilibrium, the law of least stress, Spencer's law of evolution as a passing from homogeneity to heterogeneity, with a corresponding dissipation of motion, – can only have significance for limited systems within our experience. If we apply them to reality in its wholeness, without compensation, they imply a finite beginning and end of our world. In an infinite past, any one way process of finite changes must have run its course innumerable ages ago.

Another characteristic which seems to be universal is that of rhythm. We have long been familiar with the rhythmic character of some of the large movements that give us the periodicity which is the basis of our time measurements, whether in the rhythmic functions of the organism or of our astronomic system. We have observed, too, the rhythm in the evolution of life forms where periods of stability seem to alternate with periods of mutation; and we are familiar with a similar rhythm in the social history of the race. It is only recently, however, that Planck's theory of quanta has called our attention to the same rhythmic character in the more minute and simpler systems of energy where we seem to observe the systole and diastole of nature's heart. Energy seems to proceed by finite drops rather than by continuous and infinitesimal gradations. Moments of potential and active energy alternate. It is also discontinuous as regards the quantitative conditions of its activity. Effects of a characteristic kind take place only when a certain threshold of inertia has been overcome. This is illustrated in the physiological realm by Weber's law, which formulates the fact that certain differ-

[10] Burnet's translation, line 90.

[11] *Encyclopaedia Britannica*, 11th ed., article, "Energy."

ences in sensation can be perceived only when the stimulus is increased by a definite ratio of the previous amount.

We have seen that relativity is a fundamental characteristic of energy systems. Properties vary with the system. We can speak of no properties in the abstract. Our standards of measurement are subject to variation no less than the things measured. For practical purposes, we standardize our units of measurement by making the conditions as stable as we can. But at best the conditions of which we can take account are limited. If our standards and the things to be measured vary alike with reference to conditions outside of our observation, we are necessarily ignorant of such variations, and for practical purposes they do not concern us. But theoretically the thought is uncanny and disquieting. We know of no absolute position in space or absolute system of relations. Motion is for us relative to a limited system of positions which we have selected for provisional purposes. Our generalizations, whether of facts or values, are circumscribed by the relative systems of our experience. Our standards of measurement, whether of energy, time, or space, are all alike pragmatic. They are conveniences within the particular conditions with which we happen to deal. And so long as we can find our way and perform our common tasks on the basis of them, they are practically valid. This does not mean absolute agnosticism, since such properties as we experience, and such relative relations as we can observe, must be real in any case, however fragmentary they may be, and however much more intelligible they might become in more comprehensive systems. Nor does relativity mean neutralism. It is only our intellectual abstractions that are neutral. Things for us must be known as ensembles of properties within energy systems. As such, they do real work. When we speak of activity as the common characteristic of all our real systems, it is not the abstract concept of activity which does work, but activity as uniquely determined within the special system with its movement and form. Neutralism is the emasculated ghost of the old superstition of abstract, independent entities, – the grin without the old metaphysical cat of inert substance, but none the less reminiscent of that beast. Not even mathematical entities have any meaning except as predicative functions within a system, though here the system is analytic, determined purely by our assumed initial postulates. Energetic systems are empirical. Their properties must be discovered *a posteriori*.

The Relation of Energy Systems to One Another

It is the custom of science to deal with systems of energy as closed systems. We have seen, however, that certain characteristics overlap and seem to hold for all energy systems. The question naturally arises as to the relation of these systems to one another. Can we find a common denominator? Science deals with special systems and their characteristics. The transition from one system

to another – from gases to liquids and solids, from the chemical elements to their compounds, from material systems to electrical and mental systems, with the unique ensemble of properties in each case – science takes as a matter of fact. It recognizes the discontinuities in nature as well as the continuities. Whether we are concerned with conditions that are under our control, as in the production of the compound, water, from hydrogen and oxygen in the chemical laboratory, or with conditions antecedent to our experience by vast geologic ages, and still unknown to us, as in the case of the compound, life, science accepts new beginnings as facts, and observes and catalogues the characteristics of the new system as best it can.

Philosophy cannot know more than science about matters with which science deals. It has no business to stick to inert substance when science has found the conception of energy the more fruitful one. It has no right to pass upon the facts or theories of science so far as these are based on experience, and found serviceable in meeting our practical problems. But it is the province of philosophy to try to understand science by correlating its results with each other, and with the permanent demands of the race.

It would seem, in the first place, that creative synthesis is of the very nature of reality. We must accept the new qualities and values as gifts, whether it be the compounding of mechanical forces in a new direction, or the properties of chemical compounds, or a new life unity, or a new social bond. In each case, we must take account of the properties unique to the specific situation, as well as observe the persisting constants. In each case, we must follow the lead of experience, and shape our theories accordingly. Each energy system with its properties must be taken as real. It has just such properties and relations as are manifest in the system, whether they be the simpler properties of material systems, or the more complex properties of such systems as life and mind. There is nothing occult about energy, except as our ignorance makes it so.

In the second place, systems of energy, as we find them in the real world, overlap. There are no closed systems except for our abstract purposes of description. They make definite differences to each other. They interpenetrate and interlock into one energetic world. Energies, throughout the complexities of systems, retain their primal property of doing work. They are ever expended into other energies and reimbursed from them in the great clearing house of nature. The cleavages are of our own making. They are due to our assumptions, not to reality. When, for example, science held to the hypothesis of inert substances, acting on each other by impact – inert, extended, material substances and inert, non-extended, mental substances – as its working model of reality, it was difficult to see how material energy could in any way make a difference to mental. It would be equally difficult to see how it could make any difference to electrical systems, where likewise molecular models do not seem to apply. In either case, we should have to invoke parallelism with its

absurd results to bolster up our initial assumptions. But our intellectual models cannot alter the facts. The real units of reality, we have seen, are not inert entities, but energy systems, in one type of which material properties constitute a differential characteristic. The energetic conception of reality leaves us free to follow the lead of the facts, and to recognize such continuities and discontinuities, such uniqueness and interdependence as we find. Electricity gives rise to mechanical and chemical changes; and they, in turn, serve to liberate electricity; and while the latter is more subtile and pervasive, it is the material world which canalizes our electrical energies and makes them serviceable. Plant life is dependent upon the material systems for nutriment and framework, and upon light and heat for the processes of assimilation and growth. The mental type of system leans upon the material and organic systems. It requires proper nutriment, proper conditions of temperature and light, proper bodily position, proper rhythms of rest, in order to do its work, not to mention its dependence upon neural structure. It is clear that it is the more complex systems that overlap and are correspondingly dependent upon simpler systems. Heat would seem to be the lowest and most amorphous type of energy from our point of view, as the more complex energies seem to be dissipated as heat, and thus seemingly lost as available energy. But as we have already pointed out, this can hold only for our limited perspective and powers of control.

Reality reveals itself in many systems. It is matter, it is light, it is electricity, it is mind, it is truth, right, and beauty. It is all of these and many others. All the varying phases belong to it, and one is no more real than the other. It is "day and night, winter and summer, war and peace, satiety and hunger; but it takes various shapes, just as fire, when it is mingled with different incenses, is named according to the savor of each."[12] The more complex systems furnish a greater variety of properties, but however imposing they may be, they must trail along and draw their sustenance from the simpler, even as the ivy trails along and draws its sustenance from the soil. While the more complex systems logically overlap the simpler, which they presuppose as conditions and instruments, this does not mean that the simpler have no existence of their own, but are always dissolved or taken up into the more complex. When they are so taken up, they cease to exist as simpler. Water, as an individual compound, has definite, characteristic properties; while water, taken up into other compounds, inorganic and organic, is no longer water. It has lost its individuality. But the water that satisfies thirst, with many other unique properties, has claims of its own. We do not want it merely abrogated into more complex systems. We would not want to drink water that has entered as a constituent into blood, or let the children play with water that has been taken up into nitroglycerine. In the economy of the whole, one

[12] Adaptation of Heraclitus, fr. 36, Burnet's translation.

system cannot be said to be more necessary or real than the rest. Here, at any rate, the words of Browning hold:

> "* * * Nor soul helps flesh
> More now, than flesh helps soul."

Of each, we must say, in characterizing reality: "That art thou." There is no substrate except the interlocking, interdependent energies; no unity, except the form of each, and of the multicolored whole.

The passion for simplicity, however, is incurably rooted in the human mind, and there will always be the attempt to reduce the concrete variety of the world into some primordial system, be it matter, electricity, or mind. This seems a mistaken and fruitless quest. We must adhere to the pragmatic postulate without which we could not proceed at all, *viz.* that reality is what it manifests itself to be in its varying contexts. The process is fundamentally a creative process. It is not a shuffling of neutral entities. The properties are combining properties; they are uniquely determined by the system. We have no right to dogmatize, whether in reading backward from the more complex systems to the simpler ones, or forward from the simpler to the more complex. We must find our way on the basis of experience and take reality as it exists at each stage of complexity.

We can, indeed, classify systems on the basis of common and differential traits; and we find that some can be treated as varieties of one species. Thus it has been found that electricity, light, radiant heat, and magnetism can be successfully dealt with on the basis of a common electronic theory, though their differentia are no less significant than before. It has been suggested that nervous energy may be reduced to the electrical type. Says Professor Gotch: "Physiology has definite grounds for believing that, as far as present knowledge goes, both the production and cessation of central nervous discharges are the expression of propagated changes, and that these changes reveal themselves as physico-chemical changes of an electrolytic character. The nervous process, which rightly seems to us so recondite, does not, in the light of this conception, owe its physiological mystery to a new form of energy, but to a circumstance that a mode of energy displayed in the non-living world occurs in colloidal electrolytic structures of great chemical complexity." While science thus seems to have succeeded in simplifying large domains of facts, so long seemingly heterogeneous, it has also discovered new varieties and complexities which challenge further reduction and corresponding overhauling of old categories, as in the case of radioactive energies. For pragmatic purposes, three general types of systems would seem to stand out – the material type of system with its differentia of gravitational mass and molecular motion; the electrical type of system with the electron as its energy unit; and the mental type of system where conative tendency, with its possi-

bilities of consciously directed action, cognition, and appreciation, is fundamental. But such a classification is purely a matter of convenience, and throws no light upon the process itself.

We seem to get more light when we take the evolutionary point of view. No doubt our systems of energy, as we observe them to-day, are the result of a long process of selection and survival. Darwin showed this in a classic way for the organic type of system. It is equally clear for the more complex mental systems, on the basis of which we must understand human history. Nor does the inorganic world lie outside this evolutionary conception. The properties of matter, the distribution and concentration of the elements, and the stability of the present material structure – these are all the result of a selective survival process. It does not seem probable that this marvelous adaptation of the material system to telescope into and form a fit environment for more complex systems such as life, can be accounted for on the basis of mere chance.'[13] It is "more congenial" to our mind, to use Poincaré's phrase, to assume intelligent selection within the process, however much such selection may surpass our faculties. That systems exist at all – relationships of processes statable in terms of a few simple principles – would seem in itself, as Newton long ago pointed out, an indication of rational emphasis within the world of which our reason is a part.

While the empirical generalizations about evolution must always have significance for our reading of reality, their metaphysical interpretation is often confused. Here the mechanical tendency of the human mind has come in to vitiate the reading. While we can trace a sequence from simpler to more complex systems, within a given series, we cannot say, therefore, that the properties of the more complex systems are compounded out of the properties of the simpler ones. If complex life-systems have evolved from unicellular organisms, it does not follow that they are a mere mechanical combination of the simpler organisms. New properties have been developed as a result of the organization, differentiation, and selection within the process, in its adaptation to a larger environment. These properties must be taken for what they are in each stage of development.

Owing to the early progress, as well as to the convenience, of mechanical science, it was natural that material systems should come to be emphasized as the essential type of reality, and that the more complex systems should be regarded as compounded out of material properties. But while we must recognize material properties as real within the systems where we find them, we have no reason to regard them as any more real than the unique properties or ensembles of properties which appear in more complex systems, such as life and mind. Even if the material type of system were absolutely earlier, it

[13] See in this connection "The Fitness of the Environment," by Professor Lawrence Henderson.

would not follow that it is more real. As a matter of fact, the material type of system is just as much an evolution as the organic type. And while, in our limited series of geological evolution, the material system had to evolve to a certain stage before life forms could appear, the two types of systems have for long ages evolved together and a corresponding fitness been established. Nor does it follow from the temporal antecedence of the material properties that they could give rise to the properties of the more complex systems, or that the material properties are of greater importance in understanding reality. The real energies which we deal with in evolution have other potentialities than material properties; and it is these potentialities that come to light in the creative process of the universe. It is not the properties of extension, weight, cohesiveness, etc., which constitute life, though they are present, and form an important index to our description of life processes. Life is characterized by the ensemble of properties which is unique to its own system and which cannot be said to exist at all in material systems. The properties of the simple systems must be treated as instrumental when we deal with the more complex systems. They are, as it were, handles or signs, by means of which we can lay hold of and, to a certain extent, describe and control the conditions of the more complex systems. Thus we are able to produce a chemical compound with its new properties, once we know the constituent elements and the proper conditions of temperature, etc. Thus the great nature chemist was able to produce, through the energies of a seemingly dead world, the properties of life; but the deadness exists only in our intellectualistic misconceptions. To try to account for life as a compound of material properties is as reasonable as to try to account for the characteristic thinking of a man on the basis of his size and weight. These are indeed important for certain kinds of behavior of human beings – getting a suit of clothes for example – but they do not as such account for their thinking.

The electrical theory is subject to the same criticism as the old material atomism. We cannot account for matter as a mere arithmetic sum of negative electric charges any more than we can account for life as a sum of material properties. The material atom is, on any theory, a unique system with its own combining relations with other atoms, its own unique properties, which are not the properties of free electrons; and adding an unknown element of positive electricity does not clarify the situation, any more than adding vital impulse to a material system explains life. Whether such an element is proved to exist or not, we should still have to take account of the concrete system of matter itself with its concentration, pattern, durability, and reactive properties. On any theory, the material system is uniquely real; and we must take the characteristics as they exist in the system itself. There is indeed an interesting analogy, as pointed out by J. J. Thomson and others, between the figures assumed by magnets in an electrodynamic field and the periodic law of the elements. But mathematical laws sometimes hold for decidedly disparate

systems. Witness the formula for kinetic energy. The different conductivity of different elements would not prove, any more than disprove an electrical substrate. A man carrying a log is not necessarily a log. Even if the characteristic properties of matter, such as extension and weight, can be simplified for purposes of description by being stated in terms of motion and distance, or if the material atom can be regarded for certain purposes as a halfway house for treating facts which are further dissociable into electric charges with their particular and constellation velocities, it still remains true that extension and weight are practical determinants which matter does possess, and which electric charges, as we ordinarily understand them, do not possess.

To try, again, to account for matter as mind, – "degraded" or "estranged" mind, "mind hide-bound with habit," – is at best a confusing use of language. Material systems do *not* have the properties of mental systems. They are as unique as the latter and have their own claims to reality. They are not dignified one whit by being associated with the name of mind. There is no reason, moreover, for using opprobrious epithets about matter. It has its own place and importance in the economy of reality. It is the unique distribution, concentration, and durability of the material world which makes possible the more complex systems of life and mind. Through the correlative evolution of matter, reality makes possible that other series of evolution which terminates in significant and appreciative reactions to the world The material and vegetative systems furnish the stored-up energy, the stable frame, the means of canalization of the more subtle energies. They furnish the tools, – direct in our bodily movements, indirect in the case of material instruments, – which make intelligent behavior possible.

There is one sense in which we can speak of the more complex systems as higher and more real. They reveal more fully the potencies, the actuality of the world of energies in which we live and move and have our being. They overlap logically. They imply the simpler systems, such as the material and electrical, as their background and instruments. They indicate, in a more concrete way, the direction, the formal organization of the larger world, the system of systems, from which our fragmentary systems are abstractions. It is because this system of systems, with its potencies and form, interpenetrates the humblest parts of the universe, and gives direction to the whole, that it seems as though the simpler systems produced the more complex. But what we call "matter" is more than matter. The seemingly inert energies of our world are fraught with infinite potentialities as they enter into the more and more complex systems, and yield up the for-us hidden properties, in the stress of heat, in electrolysis, in organic assimilation, in the emotional excitement of mind associations. We may well say with Browning:

> "Well, this cold clay clod was man's heart:
> Crumble it, and what comes next? Is it God?"

In the case of one system, the various systems do indeed converge into one unique relation so far as we are concerned. And that is in the cognitive system. It is mere tautology to say that for us to speak of energies they must first be known. In so far as known, they are indeed uniquely determined by the cognitive relation. But it is a false assumption to suppose that our *knowing* the forms and properties of systems constitutes their existence. We can know the systems *because* they exist and have a certain form and certain properties. This is as true of our own past as of the Milky Way. Our taking account of them is an afterthought. It does not alter the unique systems of which we take account. The stellar system, the properties of our material environment, the reactive properties of plants, the civilization of Greece, existed – they had their own properties and form – long before we took account of them. Hence, we can abstract from our personal perspectives and socialize them. We socialize our space orientation, which in the first instance depends upon the organism and its needs. To make intelligible our fleeting perceptions, we interpolate our gravitational and electrical systems. We discover their properties and mathematical form. In mental systems, we have again a unique reality which we must try to understand. Only in such systems is the ensemble of properties known as values possible. These systems are indisputably real when they exist, and are irreducible to other systems. They are "the master light of all our seeing."

In these conscious mental continuities, reality reveals to us, not only the formal relations which we discover and retrace as truth, but the demand for justice, the property to have mercy, the response of beauty. This is true not only in our human relations, but still more in those higher continuities which we call communion with God. These higher contexts must be taken to reveal the nature of reality, quite as truly as the simpler contexts which we deal with in mechanics. Each system makes its own unique creative contribution; each system furnishes a solution in which reality shows more of its reactive properties. Thus electrical systems reveal properties which lie outside our material systems. In the chemistry of the organic systems, we find marvelous powers of assimilation and response, which, so far, lie beyond our artificial imitation. In our mental systems, with their greater capacity for storing up potential energy in the way of inhibitions and facilitations of behavior, this complexity of properties increases still more. It is here that the unique responses of value arise as creative additions to our world. These are as much a part of the reality of the world as the chemical responses. They constitute for us its choicest part. The universe, in its varying systems of creativeness, calls to our mind the Chinese swallow which gives us our edible nests. First it produces a nest of largely external material and contributes but little of its substance to the frame. In its second building, after being deprived of its first nest, it labors harder and secretes more of itself. In the third nest, in the pain and anxiety of frustration, it yields up its very lifeblood and

colors the nest with its crimson. So in the rare solutions of our intense emotional excitement, the energy of the universe, in the pain and stress of clashing interests and the threatened defeat of its ideal instincts, contributes its very soul as it labors to give birth to new values, and colors the gray world of matter with its rainbow glory. Here the systems of the universe not only exist but have significance.

And who shall say that our limited mental systems are the last word of reality's revelation? The energy which shows its marvelous properties in all these systems and which, even in the simplest, reveals a sublimity which humbles our power and insight, may well be capable of higher creative syntheses, more comprehensive actualities and insights than those associated with our organisms and our social institutions. That such a synthesis is real, we have intimation in the vast correlative adjustments of nature of which we get glimpses in science, and in those instinctive demands for harmony and beauty which make themselves but feebly felt in us. We can see and appreciate but piecemeal and in the dark glass of our prejudices. The directive power of the universe of which we have intimations in our higher continuities no doubt has a more adequate way. In the meantime we must have faith in our own insight, relative though it be.

In this brief survey of energy, we have implied throughout other categories than energy properties. Only so could we understand energy in action or as doing work. Otherwise it would be congealed, – frozen energy. We have implied geometrical properties and time properties which must figure in energy systems. We have also implied form, without which energy systems would be insatiable. Elsewhere we have given more adequate consideration to these characteristics. We must here turn to a further analysis of energy properties, as they appear in the world of things and minds.

BIOGRAPHICAL

John Elof Boodin. "Biographical." *Contemporary American Philosophy: Personal Statements*, ed. George P. Adams and William P. Montague (New York: Macmillan, 1930), vol. 1, pp. 136–142.

What is a life? No one knows. It emerges from the darkness like a meteor, makes a transient trail and disappears into the darkness again. What has philosophy to do with life? Sometimes philosophy is an expression of life, but more often it is make-belief, a compensation for the failure of life. An autobiography of spirit must at best be an after-thought and is of doubtful value. If I could point to a master, or masters, as the source of my philosophy, the task would be simple. But I can call no man master, though I have learned from many masters. What I have done is the result of a lifetime of meditation with its significant moments now and then, for the most part too fleeting and too much a part of the texture of life to receive a date.

I was born on a farm in the parish of Pjetteryd in the picturesque highlands of Southern Sweden. My ancestors had lived in that neighborhood for generations and had been leading citizens, but their education had not extended beyond the parish schools. The clergyman's children were the only ones who went away to college. My father owned a considerable estate with a large pine forest, and would have been prosperous had his family not been so large. He married a second time in middle life, and I was the child of a young mother and a father advanced in years. I was nurtured on the Bible and the legends of the place. There were the groves and altars of the old Stone Age and there was the much older background of the trolls that lived once in the hills and in the bordering lake. My father told me the folklore of the place as his mother had told it to him, leaving my child's fancy free. Thus I learned respect for time.

I helped in the work on the farm until I was fourteen, and learned to love nature and respect the processes of nature, with its seasons of seed-time and harvest. There was not much machinery and the contact with nature was intimate. Through this training I became an empirical realist. I also learned the law of mutual aid. My parents were a sort of Providence to the neighborhood, looking after the poor, the sick, and the dying, and I was the messenger boy. They were people of simple piety who believed that nature and man are included in a beneficent personal order in which there were evil forces as well as good, but the good prevailed. In this way I probably laid the

unconscious foundation of a cosmic idealism. I came to love poetry and write verse, and acquired a feeling for the beauty of language. I roamed much in the woods, where I rounded up the cattle at night and knew all the wild-strawberry patches. I was given to day-dreaming about theological things, which occupied a large part in my education. This day-dreaming eventually became philosophy, which has sustained me in the vicissitudes of my career.

I graduated from the parish schools at the age of twelve. This might have been the end of my schooling, but a young curate, Pastor Bomgren, who conducted the examination, became very much interested in me and told my father that I had a better mind than he (the curate) and that it would be a pity to make a farmer out of me. He offered to take me into his family to tutor me for the gymnasium. He died before his plan could be put into effect. But he had changed my life. He seemed so grand to me that I could not believe what he said, but I knew that somehow I must have an education. His successor, Pastor Sjöfors, with his kind wife, carried out his intention, and after some tutoring I entered the second year of Fjellstedt gynmasium in Upsala, of which Kjerfstedt was the kind and masterful rector. I was the leader of my class, but the second year I fell ill and was sent home. Shortly afterwards my father died; and I decided to emigrate to America.

In the summer of 1887 I came over in the steerage and landed in a mining town in Illinois, where I worked in a blacksmith's shop for two years, getting what schooling I could on the side. The realism of wielding the sledge was added to the realism of the farm. I also learned a great deal about human nature in its rough, though honest and kindly, form. I graduated from a Normal school and taught for a year before I found my way back to college. I entered the University of Colorado as a sophomore in 1892. My most significant contact there was a course in Comparative Literature with Raymond Brackett, in which I was encouraged in interpretative writing and recommended to the editorship of the literary magazine as "the best writer of English in college." But I had spent my earnings. I was called to Minneapolis to help in the work of the Episcopal Church among the Swedish immigrants, and so found myself in the University of Minnesota in 1893–94. This was an important year because I was introduced to the social sciences by the beloved W. W. Folwell, to the psychology of William James by James Rowland Angell, and to Greek philosophy, both in survey and in the original. I wanted to go east, if possible to William James. An opportunity offered itself to go to Brown University in 1894. I became a student of James Seth for two years and discovered philosophy. I found that it was what I had always wanted. Really, it was my own philosophy of which I began to become conscious and which I tried to express in opposition to my beloved teacher and the great masters. It is characteristic of my mind that it has developed chiefly by opposition. The first masters with whom I wrestled were Kant and Hegel, whose works we took up for detailed study in seminars. I was fortunate

in receiving my early training under so fair-minded and objective a teacher as James Seth. Seth taught me the importance of sympathetic understanding of those with whom I disagreed, and later G. H. Palmer pointed out that every philosophy means a great deal to the man who creates it. My earliest meeting with William James, whom I had wanted to know for years, was on the occasion of my presenting a criticism of his essay "Is Life Worth Living?" at our Philosophical Society at Brown in 1896. I succeeded in rousing him to an animated reply. When he returned at the end of the school year to give the annual address before the Philosophical Society, he introduced his paper, "The Will to Believe," by saying that it was written to meet objections which had been raised on his previous visit. He was my friend for life.

In 1897 my dream to enter Harvard was fulfilled, in part through the interest of C. C. Everett, who secured me a Hopkins Scholarship and followed my course throughout with paternal solicitude. William James greeted me affectionately and was most sympathetic to my venture into philosophy. It was the heyday of philosophy at Harvard, the day of James, Royce, Everett, Palmer, Münsterberg, Santayana. Among graduate students I was contemporary with Bush, Lovejoy, Montague, Holt, Perry, Sheldon, Savery, Rieber, Horne. Strangely enough I lived mostly with my own thoughts and took little advantage of this brilliant array of philosophers. The only course I had with William James was a seminar in psychology. I attended seminars of the other men, except Santayana, whom I met only occasionally and with whom I had only one heart-to-heart talk on philosophy. William James kept in kindly touch with me, inviting me to his home to talk over my incipient ideas. But Josiah Royce was the master with whom I wrestled for the salvation of my soul from 1897 to 1900. It was in his seminar especially that I developed and expressed the beginnings of my metaphysics. It was in opposition to absolute idealism that I developed my theory of a real non-serial time which I first advanced in Royce's Hegel Seminar in the spring of 1898. Royce had invited James to be present on the occasion. James, of course, was warmly sympathetic. I had expected to be caught in the coils of Royce's dialectic. No man at Harvard could stand up against Royce in argument. Instead of attacking me, however, Royce devoted himself to a sympathetic exposition of my idea and paid me the high compliment that I had discovered a new concept. I worked on it the following year and presented part of my material as my doctor's thesis in 1899. Royce was good enough to say before the seminar that in his Gifford lectures he had modified his exposition of time to meet my criticisms. I was appointed Walker Fellow and Lecturer for the following year, being given the opportunity to present my material to Royce's seminar while he delivered the second series of his Gifford lectures in Scotland. In 1900 I was awarded the Austin Teaching Fellowship, but on the insistence of G. H. Palmer, who was chairman of the department, I gave that up and accepted a professorship at Grinnel College in Iowa.

It is impossible to measure the influences that act on our minds and determine our course. The greatest contribution that Harvard – James and Royce in particular – made to my development was the faith which they so generously manifested. On a visit to me in the West, some time after I had left Harvard, Royce, in the kindness of his heart and fearing, no doubt, that I might be discouraged in my isolation, said in an awkward, bashful way that he felt he owed it to me to let me know that at the time I took my degree it was the opinion of the department that I was the best metaphysical mind that had come to Harvard so far, and that he thought it still true, but that he could not vouch for the future. This to me was the verification of the prophecy of the young curate, and has been to me what the oracle of Delphi was to Socrates. Whether I have proved or disproved the oracle, it has given me courage to keep on with my search for truth through years of neglect. It may seem frank to say this, but I am trying to write as honest an autobiography as I am able.

My active teaching career has been spent in the West, with rare leaves of absence – four years at Grinnell College, nine years at the University of Kansas, fifteen years at Carleton College (including the year 1927–28 when I was visiting professor at the University of Southern California), and from 1928 at the University of California at Los Angeles. My philosophy has thus taken form on the prairies of the great Middle West – the heart of old America – with its strong common sense and conservative social philosophy. The expansiveness of nature, with its unimpeded vistas and yet its sense of homely friendliness, must, it would seem, in the course of years get into a man's spiritual outlook. So far as my social relations are concerned, they have been mostly with the Western students whose hearts and minds have been as expansive as the prairies. I have never felt consciously restricted in my thought. What the unconscious effect of the massive conservatism of the West has been, I cannot say. The fundamental postulates of my mind were probably formed unconsciously in the earlier period of my life, and the West has been a continuation of my early life. Individual genius follows its own course, and if the environment is not congenial to its fundamental traits it will express itself in violent antagonism rather than agreement. I have always tried to be honest with myself and others, and my students have responded with honesty and affection.

I ought, perhaps, to say something about my relation to pragmatism; but I own that I feel a strong repugnance to doing so. For I meant to do a generous thing and received only misunderstanding as my reward. The thing to have done would have been to attack pragmatism, and then I should have received some recognition. But pragmatism was attacked on all sides and the debate only led to more confusion, so I thought I would try the method of sympathetic interpretation. Pragmatism certainly claimed to be a rediscovery of everything that is sane, and I tried to view it in that light. The method of

C. S. Peirce aimed at clarification of meanings and might be used on pragmatism. I felt a deep friendship for William James. He was not well and was very much depressed at what seemed to him wilful misunderstanding of "us," meaning Schiller, Dewey, and himself, He wrote me rather pathetically that he wished I could see my "way clear to join the movement." I had a sporting interest in fair play, and felt that I ought to do what I could to help in clarifying the issue. So I wrote some papers in which I tried to interpret pragmatism in a realistic and objective manner. One of these papers: "What Pragmatism Is and Is Not," I submitted to William James. He replied enthusiastically, and said that I had "played all the variations and hit it right on every point," and that I was "one of the very few who have understood what we meant." I published the paper in the *Journal of Philosophy*, 1909. Schiller, though not enthusiastic, thought that I had defined pragmatism fairly, but that humanism means something more. Other pragmatists seemed to resent my interpretation. It appears that in attempting to clear pragmatism of misunderstandings I had "evaporated the richness of its meaning" for them. There was, I think, the further feeling that pragmatism – like the protective tariff – should be revised by its friends and not by an outsider. Many years later, in his *Reconstruction of Philosophy*, Dewey made many of the restrictions which I had made with an "of course," which was characteristic of pragmatism. I have at any rate the satisfaction that if I did not please the pragmatists I did not sacrifice truth as I saw it. Whether I had any influence in turning pragmatism into a more realistic direction, I do not know. The papers on pragmatism were included in *Truth and Reality*,1911. But my interest has always been metaphysical rather than epistemological, and I returned to my main purpose.

Pragmatism is now dead, and it is not seemly to speak ill of the dead. No one seems to want to own it now, except writers of French doctor's theses. Schiller is a "humanist" and Dewey a "naturalistic empiricist." William James exists in glory in spite of pragmatism. But pragmatism, though dead as a movement, has left us an adjective which is used a great deal by men of science – the adjective "pragmatic." Intellectualism has emphasized too exclusively the aesthetic aspect of truth as coherence and simplicity. "Pragmatic" emphasizes the other aspect, the convenience of an hypothesis in dealing with the emergencies of experience. Truth as we have it is never an exact picture of the nature of things, but it enables us to proceed in the direction of further acquaintance with reality. Pragmatism is America's most characteristic contribution to philosophy; and its effects have been felt, not only in philosophy, but still more in such practical fields as education, religion, and law. Long live pragmatism!

There has been, I believe, a continuous and consistent development in my philosophy during the last thirty years, though I have made no conscious effort toward consistency. My ideas have come to my mind as a result of an inner

and mostly unconscious dialectic. But sometimes some precipitating circumstance is evident. It was the reading in 1897 of Royce's *Conception of God*, especially the Supplementary Essay, which called forth my first paper on the reality of time as against absolutism – Hegel, T. H. Green, and Royce. My reading of Alexander's *Space, Time, and Deity*, in 1920, called forth my paper "Cosmic Evolution," upholding cosmic interaction as against mere emergence. My critical reaction to pragmatism made me conscious of the importance of recognizing the structure of truth as well as its function. Contemporary movements have been chiefly useful as irritants, when I have been conscious of them. If my development in retrospect seems consistent, the consciousness of this development has been decidedly discontinuous. The first idea comes as an overpowering intuition with great emotional vividness. I seize upon a piece of paper and write it down. Then through weeks, perhaps years, I build a scaffolding for it. And then perhaps the reader wonders why the idea should impress me so much when it has such a natural place in history. But the setting is all an after-thought.

The first expression of my philosophy took the form of temporal realism in my papers before Royce's Seminar and in my doctor's thesis on "The Concept of Time," 1899. These remain unpublished, but the fundamental idea was developed in the monograph, *Time and Reality*, published in 1904. (The idea was afterwards restated in Part IV of *A Realistic Universe*.) My first published paper, "The Reality of Religious Ideals" in the Grinnel *Unit*, 1900, indicates the main trend of my realism. The paper was afterwards enlarged and became the last chapter in *Truth and Reality*. My empirical realism and metaphysical energism, with the functional conception of qualities and values, found provisional expression in a series of papers in various journals. These papers were subsequently revised or rewritten and issued in *Truth and Reality*, 1911, and, more especially, *A Realistic Universe*, 1916. (The preface in each case indicates the previous publication.) My cosmic idealism found expression in *Cosmic Evolution*, 1925. The date of the books is no indication of the birth of the ideas or even their publication. Thus Chapters I, IV, and IX, which indicate the main trend of *Cosmic Evolution*, were published in 1921, while the manuscript of the book went to the publishers the latter part of 1924.

In the main, twentieth-century science has furnished the content of my philosophy, but this has been assimilated to the other types of human experience and to the historic structure of philosophy. Though thought is a living process and must be tested by its actual success in systematizing present evidence, it is a matter of surprise how much of what seems original is foreshadowed by the geniuses of the past. Philosophy is akin to poetry in its divination of the future.

NATURE AND REASON

John Elof Boodin. "Nature and Reason." *Contemporary American Philosophy: Personal Statements*, ed. George P. Adams and William P. Montague (New York: Macmillan, 1930), vol. 1, pp. 143–166.

Nature and Human Nature

It is because we live within the matrix of nature that we can hope to understand nature. We must take account of nature as it is from our frame of reference, including our human organization, biological and social. There has been a tendency of late to emphasize nature as it appears at the level of electrons. But nature is not any more real at the level of electrons than it is at the level of human personalities. In any case we know nature only functionally, i.e. through its reactions. If there is anything that science teaches clearly at present, it is that nature is energy. It is not some sort of stuff, and certainly not neutral stuff. Nature is what it does. To understand the activities in nature we must take account of the whole relevant situation in nature. Human organisms are structures in nature and of nature. They are reagents in the matrix of nature. The appearances of nature in relation to human nature are real appearances. But the appearances vary at different levels of nature owing to the character of the reagent. Nature appears with a variety, definiteness, and objectivity to an organism, with specialized sense organs and a highly developed nervous system that it cannot have to a jelly-fish. Pathological evidence shows that cerebral structure with its patterns makes possible an epicritic reaction to stimuli, i.e. a reaction to the location, intensity, and rhythm of stimuli, in contrast to the protopathic all-or-none reaction when the cerebrum fails to function. When we talk about nature, we generally mean nature as it appears to a normal, developed human individual. The baby does not react to nature as a mature individual does, partly because its brain is still undeveloped, partly because it lacks the social schema which the mature person brings to nature. The appearances of nature vary with the duration and structure of the reacting individual in the matrix of nature. At each level of nature the individual might say to nature: "that art thou."

As our attempt to know nature is primarily a relation of nature to a human organism with its physiological and mental patterns, the trail of human nature is, indeed, over all our knowledge. This is no reason for agnosticism in regard to our knowledge of nature, since human nature is part of nature, and the reactions to human nature are real relations within nature. Difficulties

arise only when we try to imagine what nature is to a reagent which is not human. Our categories and judgments, so far as they prove relevant to nature in its relations to us, are true of nature – in those relations. We try also to know nature in its relation to other reagents. But we must bear in mind that we are observing the appearance to a human agent of these reactions in other contexts. Our faith in knowledge implies that nature in its totality has a constitution akin to the human mind, and that our thinking of nature is relevant to nature in that sense. But there still remain the part-relations within nature on simpler levels of nature which we try to describe as best we can. At best our knowledge of nature on the lower levels is pragmatic, i.e. useful for prediction and perhaps control. We cannot have direct acquaintance with nature at these levels. In humanizing these levels, as we do in taking them into our schemes of knowledge, we are dealing with their character for us. What we must be careful to avoid is to discredit the relations of nature within the level in which we live and think in favor of the simpler relations. The epicritic reactions to nature are not less real than the protopathic. The former are the true appearances of nature at the level on which they appear, and they are the more adequate appearances.

The mechanical theory made it appear that the individual reactions in nature become more definite and predictable the lower down in the scale we go, but that was because mechanism is an intellectual transcript which we put into nature. The mechanistic interpretation of nature is as anthropomorphic as the romantic interpretation. Recent physics has shown that on the simplest level of nature the individual reactions are diffuse and uncertain, and that it is only because we deal with mass reactions in our treatment of matter that the reactions have for us the definiteness and predictability which they appear to have. The determinateness is statistical. It is, of course, absurd to speak of this indefiniteness of nature at the simplest level as freedom. Freedom can come only with organization, and choice based upon organization. But it is a gain to have destroyed the fetich of mechanism in nature.

We must bear in mind that we live on a macroscopic plane in nature, and our adjustments are to this plane. Electrons can be experimented with only in relatively abstract conditions in nature – a relative vacuum, shot through with enormous potentials of energy. At the temperature of the hot stars, structure and determinateness may be impossible. The physicist's findings seem at present contradictory and confused. Perhaps that is because the physicist has tried to interpret the lowest level in terms of categories borrowed from higher levels. Electrons figure in our living only in mass organizations with their unique properties. On this plane our convictions as regards temporal and spatial relations, of causal determinations, of the community of minds have relevance, whatever the results of physics may be within the elementary plane of nature. It is on the plane of human organization that we have science and philosophy. Electrons or jelly-fish, or even chimpanzees,

cannot make the reactions of science and philosophy. Science does not question the primary convictions which have been born out of our life in nature. It deals with specific problems. Philosophies must be criticized on the basis of their success in weaving into as simple, coherent, and adequate a scheme as possible our beliefs and judgments about the world in which we live. It is not the business of philosophy to make absurd the convictions by which we live on the level of human nature, but to make them explicit. Obviously it must do so from the point of view of our human intelligence since we have recourse to no other.

Philosophers' Rationalizations

In order that philosophy may clarify nature it must place itself in the midst of the living continuities of nature, and not separate itself from nature. It is the glory of ancient Greek thought that it never separated man from his environment, nor thought from nature. Its conviction, that reality must be taken in its integrity in order to be understood, is sound, however crude the results. Even Parmenides, in spite of his skepticism as regards the senses, is clear that thought must not be separated from the world it is to know. And Protagoras, in spite of his emphasis on human nature, is confident that nature is as it appears to human nature. The great rationalists, Socrates, Plato, and Aristotle, while they emphasized that knowledge means an insight into structure, and not a mere heaping up of perceptions, held to the conviction that it is the structure of reality which we strive to know, and not something inside our heads. But here the Golden Age of philosophy closes. Neoplatonism sought refuge from the problems of a complex and perplexing world in a mystical trance without distinctions. And scholastic philosophy was preoccupied with setting in order dogmatic theological beliefs. But neither of them separated intelligence from the world it strives to know.

Modern philosophy got on the wrong track at the outset on account of a false psychology. Descartes was a great physiologist, and discovered a great deal about the nervous system. He also had a good intention, viz. to place the soul in nature. But his conception of the soul as a point-entity situated in the centre of the brain made the relation absurd. That he made the mistake of making the pineal gland the centre of the brain is of little importance. Aristotle thought of the brain as a refrigerator for cooling off the blood, and supposed that the heart is the centre of the soul, but he had the right psychology, viz. that the soul is the dominance of a certain form or structure which makes the organism function at a new level. Plotinus was more nearly right than Descartes when he located the body within the soul, for mental activity includes the whole organism with a plus quality which distinguishes mental activity from merely automatic activity, which mental activity uses. Mind is a structure in nature involving, not merely the physiological mechanisms, but

the social environment and the cosmic environment. It is reality functioning in a unique way in a *milieu* of unique structure. Descartes' conception of the soul as an inextended thinking substance in an extended inert body made any commerce of the soul with its environment impossible, and therefore made knowledge impossible. And the absurdity was not lessened by the parallelism of Spinoza or the pre-established harmony of Leibniz. It is safe to say that the mechanistic physiology of Descartes has been and remains the greatest obstacle to a sound psychology and a sound philosophy. By isolating mind from its environment, it has been the source of the false subjectivism that has dominated modern philosophy. The remedy proposed by behaviorism, viz. to eliminate mind altogether, is not likely to lead to an intelligent appraisal of reality. The only hope is that physiology may in the course of time follow the lead of the new physics instead of the old, and discard mechanism as a scientific concept altogether.

Descartes' isolation of the soul from its *milieu* in nature led to Locke's spurious distinction of primary and secondary qualities. The former are supposed to be duplicated in external nature, and to be constant and invariable in things, independently of the organism; the latter are supposed to exist only in consciousness, and to be the result of the action of the qualities of nature upon the organism. Both primary and secondary qualities for Locke serve to characterize things, and are the only pragmatic basis of our consciousness of things. But both are events or "ideas" in consciousness. Locke's conception of knowledge as nothing but the agreement or repugnancy of our ideas insulates knowledge from the world which it is to know and makes it unreal. Experience becomes a container instead of a relation as it really is. While Locke still believes in the correspondence of the primary qualities and their arrangement with their archetypes in nature, it is obvious that this external world cannot enter the field of knowledge which is concerned only with "ideas." Berkeley draws the inevitable conclusion, and the external world becomes only a set of sense qualities. Since these are conceived as "ideas" or psychological events, Berkeley thinks they must exist in a mind and have a mind as a cause; and since this cause cannot be our private mind, it must be the divine mind which causes the "ideas" in us with the regularity and objectivity which we observe. Hume returns to the naturalism of Locke as regards sense qualities. But for Hume they are just "impressions," while mind resolves itself into a string of distinct psychological events, the only difference between psychological events and sensible events being a difference in vividness, i.e. a functional difference. Nature figures merely as assumptions of unknown powers. The order of nature is not in the events of experience, for these are distinct and separate. Our feeling of causality is due to "unknown qualities" or "a natural instinct" of human nature, and is added to the constant conjunction of events in experience. The conjunction of events is contingent and may surprise us at any time.

Psychology has usurped the place of metaphysics; and Hume's psychology does not rise beyond animal instinct, and the conditioning effect of habit. We cannot speak of structure, either in the human mind or in nature. The world is a meaningless show. It is true that we retain an animal faith in the show, but that is due to irrational instinct. Hume exposed the futility of the intellectualistic assumptions of his day and made philosophy a huge joke. We shall have to ask Hume to consign his own philosophy to the flames with other useless knowledge. What a pity that Hume could not have made his sound instinct for reality the starting-point of his philosophy instead of a refuge from it!

Kant added *Gestalt* psychology to Hume's psychology of habit. But unfortunately he accepts Hume's conception of experience as a succession of separate and distinct events, and the separation of these from reality. Hence the forms must be superimposed arbitrarily upon the events. Kant was right when he maintained that nature exists for us as determined by the structure of human nature. But Kant commits two errors in his account of the forms which human nature contributes to nature. One is a mistake in analysis. He confuses the contribution which is due to tradition – in his case the Newtonian tradition – with reflex action. The other mistake is in supposing that the structure of the human organism must be irrelevant to nature-as-it-really-is. This artificial separation of human nature from nature results in Kant's regarding the particular appearances of nature as "faked" by human nature in being "given" to human nature, and it results in his regarding the structure of human nature as arbitrarily imposed upon the data of nature. Hence the world as experienced, and as investigated by science, becomes a show world. The unity of apperception becomes a magic circle, separating the cognitive process from reality. But human nature is part of nature, and the appearances to human nature are true appearances. Nature is not "given" to human nature in the cognitive process; but the cognitive process is nature functioning at a certain level. Mind is the crest of the wave of nature, or rather the dominant chord in a matrix of waves having a unique organization and quality. It is the whole-situation in nature which has form, not something in our heads. Kant's spurious invention of an intelligence which should create its own data as well as its forms was intended to get rid of the artificial separation. But it was a purely gratuitous invention of which Kant himself made no further use. We can conceive of no such intelligence. But his suggestion led the romanticists, who felt no restraint of fact, to put themselves in the place of the Almighty and by the "omnipotence of thought" create their own world *a priori* with supreme contempt for experimental science.

Present philosophy is a whited sepulchre, calcimined with a coating of science and mathematics, but within are the dead bones of the past, and the ghosts walk abroad. The Cartesian dualism and the artificial empiricism which was based upon it form the background of "critical realism." There is

no agreement among "critical realists" as to what we know. Some seem to think that we know certain primary qualities, such as shape, size, and position. Some think that we do not know the properties of nature at all, but know their order. The percepts, the ultimate data of knowledge, are mere "patches in the brain," in the picturesque language of Bertrand Russell. How we get out of our heads to perceive the structure in nature is a mystery. Perhaps it is just certain philosophers who are out of their heads. Some think we know reality only under the guise of certain essences which, though they emerge somehow in the reaction of the organism to nature, do not exist in nature, but in some eternal realm of their own, wherever that may be (evidently in the head of some philosophers). The "direct" or "naive" or "new" realists, on the other hand, insist that they intuit the properties as they are in nature, independently of human nature. For them the percipient organism is a neutral medium. All relations are external relations, i.e. make no difference to the terms related. The Cartesian substances have become neutral stuff – mere transparent ghosts. But the ghosts remain. In the meantime romanticism, with a philosophy based upon wish-psychology, lingers on. But the almightiness of thought is not so impressive as it was in the nineteenth century. None of the current philosophies have really connected with the energetic theory of the science of to-day. Meanwhile, a crude behaviorist psychology is inoculating the popular mind with crass nineteenth-century materialism. It might be well for academic philosophers to take a holiday and go into retirement, until the dialectic of scientific and social advance shall produce an appropriate philosophy as in the days of ancient Greece. But as the chief end of academic philosophy is to furnish a living for professors of philosophy, such a renunciation is scarcely to be hoped for. In any case it would not avail unless we could muzzle certain popularizers of science who are corrupting their science with the old subjectivist traditions.

Prolegomena to Future Philosophy[1]

If we are to philosophize we must recover the sense of reality of the plain man and the unsophisticated scientist. We must place ourselves in our theory where we live in fact, viz. in the energy *millieux* of nature. Our psychological organism responds with its duration and organization within nature. It is not neutral. There is nothing neutral in nature. Everything is more or less determinate activity. Nature is what it appears to be in its various *milieux*, including those of which a percipient organism is an aspect. It does not hide behind its appearances. But the real appears. In this Hegel had the true

[1] For a fuller statement see *A Realistic Universe* (Macmillan), 1916, and *Cosmic Evolution* (Macmillan), 1925.

insight. The perceptual appearances of nature are not patches in a brain. They are characteristics of a total situation in nature in which we distinguish stimuli, sense organs, nerves, brain, and a mental structure with its tradition. But these are not separate entities. The psychological organism, with its individual duration, structure, and initiative, is for science a "bulge" in a cosmic field of energy. The soul expresses nature in a certain *milieu* of nature. It is not a rank outsider. It is not a string of psychological events in a brain, but a dynamic structure of an organic situation in nature. Even an imaginative event is not a patch in a brain, but an aspect of the activity of the entire organism, including the sense organs, as well as the nervous system and the brain.[2] Mental continuities in social communication exist in nature as truly as electromagnetic continuities. We have been misled by mechanical metaphors to discredit mental communication and to imagine minds as patches in brains, interrupted by the mechanical nexus in nature. But our recognition of the immediacy of mental continuities is as irresistible as that of sense continuities when they exist. Language is not the essence of mental continuities but the code, which must, of course, be built up by a conditioning process. But it is the quality of mental continuities which enables us to distinguish them from one another, and from mere wind for which we also have language. This does not mean ghost communication. It is the specific situation in nature which has a mental quality just as another situation has the quality of color. In either case we must interpolate a medium which will help us to explain the experience, not one which will make the experience impossible.

We must distinguish our primary convictions, which are born out of the matrices of nature (including society) in which we live and act, from our rationalization of these convictions. Folklore is encrusted with rationalizations which we assimilate so early in our experience that they seem primitive to us. Such encrusted rationalizations require criticism. The primitive convictions no one doubts in his heart nor ceases to act upon them. Among these convictions are the following: that we live in a world of interacting things, some of which are social, that we know these things through creative insight into their behavior, that these things are changing things, but with such constancy that we can in a measure learn to anticipate their behavior in specific situations, and that they are spread out with reference to one another and ourselves at various distances. The rationalizations of these convictions have been various. There have been different theories about the nature of things, about the agency of things, about their flux and constancy, about their temporal and spatial relations. Rationalizing philosophers have professed to doubt the reality of the physical world with its apparent properties and its temporal and spatial characters. But their conduct has corresponded to their primitive

[2] *Cosmic Evolution*, pp. 147–154.

convictions. I have found that my noble friends among the epistemological idealists live very much as I do, in spite of their theories that matter, space, and time are mere appearances. They require food and shelter like other men. They buy coal to keep warm, and they do not treat coal as spirit. They use various means of locomotion to get to places, in spite of their theoretical disbelief in the reality of space. They worry about the passing years and about getting old, in spite of the supposed ideality of time. Worst of all they die and deprive me of their companionship, at least in the familiar way. Their faith in an eternal order of meaning and value is sublime and inspiring. But their conception of it does not seem to explain the world in which we live. Their philosophy is more of compensation than an explanation. What men live by is their real metaphysics. Their rationalizations must be treated critically.

It is the province of science and philosophy to rationalize the matrix of nature in which we exist and act. But we must not forget that our rationalizations grow out of the tradition in which we live. We are prone to find that reasonable which is congenial to our prejudices. Throughout the process of rationalization, certain primitive convictions persist. They are the real *a priori* element in the cognitive process. But man cannot live by primitive convictions alone. He must attempt to understand his relation to the world. To this end he must try to re-create the structure of nature by imaginative hypotheses. These in turn must be criticized both from the point of view of their coherence and from the point of view of their suitableness to predict the behavior of nature. In the limited state of our knowledge, the latter criterion is more important. We may have to work with inconsistent hypotheses for the time being. This is illustrated in present physical theory. Both the electron, the unit of material energy, and the photon, which is the unit of radiant energy, may be regarded for some purposes as waves and for other purposes as corpuscles. It has been suggested that they travel as waves and react as corpuscles. We have at present no satisfactory theory of either material or radiant energy. To be satisfactory our hypotheses must be both coherent and serviceable. The more successful our rationalization is in these two respects, the more we feel that we have imitated, in our conceptual structure, the structure of nature.

The knowledge relation is a momentous and unique relation among the relations in nature. To say that the cognitive relation is neutral and makes no difference to nature is absurd. Nature as it manifests itself in the cognitive situation has a clearness, definiteness, organization, and value which it cannot have in other *milieux*. One cannot over-estimate the effect that conception and language have in articulating the distinctions in nature, though they have, in the sophisticated mind, given rise to false separations. What we must bear in mind is that nature is pluralistic, that it exists in an indefinite number of other *milieux* besides the cognitive, and that the other *milleux* have their own conditions and characteristics of which we must take account indirectly, i.e.

because of the differences they make to the cognitive *milieux*. The wood burns to ashes whether we watch the process or not; and we must try *a posteriori* to understand the conditions of the *milieu* in which wood burns. How difficult this is can be appreciated only by one who is familiar with the present problems of the physical sciences. So far as knowledge is true, in the sense of the above criteria, it deals with reality as it is. Since knowledge involves a creative element, an imaginative venture, it is liable to error, and must be corrected in terms of the primary experiences. In this sense it is instrumental. But the love of knowledge is an end in itself, and has its own value. The relation of philosophy to common sense and scientific knowledge should be to criticize the partial knowledge with a view to wholeness of knowledge. But in its effort to attain complete insight into reality, philosophy is concerned, not merely with science, but with art and mystical experience and their contribution to the meaning of life.

The fundamental conception of reality in the science of to-day is that of individual systems of activity in action, reaction, and interaction with one another. An activity system is the ultimate unit of existence, but activity systems are complex to thought, and can be analyzed into certain attributes. These are our conceptual abstractions for the purposes of description and cannot give us the uniqueness of the individual reality. This uniqueness can be grasped only in aesthetic and practical realization. It is an insight gained through appreciation, not mere analysis. But if conceptual thought is unable to reproduce the individual synthesis, it can describe and predict the behavior of things. In analyzing an activity system, we find we must take account of three types of variables – energy, time, and space. Henri Poincaré threw out the fruitful suggestion that energy means constancy. Einstein has shown that inertia or mass is energy of the opposite sign, thus getting rid of the dualism of matter and energy. In describing any activity, such as a falling body, a chemical composition, a type of radiant energy, we find that there is a variable or a set of variables (which are constant under determinate conditions), such as gravity, chemical elements, quanta of radiant energy. But these empirical constants by themselves do not constitute activity.

We must also take account of its spatial and temporal aspects. It is fashionable now to hyphenate the latter into space-time in describing translations in space. We have then four coordinates in terms of which we describe motion. Our mathematical picture is a purely descriptive device and, as Einstein says, has "no physical significance." Suffice it to say that in order to have description we must have certain identifiable constants which we can track through space and time. Such factors do not exist in isolation. They are aspects of activity systems, i.e. they always involve time and space. In material systems, electrons are the units for description. We must remember that constancy is here used in a relative sense. According to the theory of relativity there are no absolute constants. The units of mass, length, and duration

vary with the perspective in a world of relative motion. They also vary with the field. We cannot regard our variables in isolation from the structure of the field in which the activity takes place.

The analysis by science is pragmatic and does not pretend to give the full implications of the postulates involved. It is an edge, as William James would have said, by means of which we lay hold of reality, but it is a thin edge. The spatial and temporal aspects, as dealt with by the physical sciences, are especially thin and all but obscured in the artificial conventions which have been substituted for them in the interest of description. There is particularly a tendency to spatialize time, and thus lose sight of its metaphysical significance, as Bergson has so well pointed out. The merit of science is that it has recognized that, in some sense, space and time are essential aspects of activity systems. The relations in the real world are never a complete close-up as in the being of Parmenides. The action in activity systems is always over space, and always involves the passage of events. That is the intuitive basis of scientific description. The mathematical conventions which it uses are instrumental towards predicting occurrences whether within an individual system or between systems. I can now claim the support of Einstein in holding that in order to describe dynamic relations in nature, we must postulate a medium of space as well as matter. Without spatial distance, there could be no metric concepts. The nature of space must be ascertained empirically. What science requires is a metaphysical continuum in which (to use Einstein's language) there are "no parts that can be tracked through time." Space has "no mechanical or kinematical properties," no inertia. It has absolute conductivity. It lends itself to three dimensional locations. Einstein adds a peculiar property of his own, viz. that space or space-ether is capable of having its geometrical structure altered in the neighborhood of matter. But whether this is true of space or of a physical medium in space remains to be established. We must, I think, accept the physicist's and astronomer's finding as to the nature of space. The measurement of space in terms of conventional units is secondary, and presupposes the objective reality of space. The extensive units of measurement are derived from bodies in space and not from space, which has no units.

Time is the passage of energy whether quanta of material energy or quanta of radiant energy. If we view nature merely on the simplest level the passage has no direction. It is only when we view nature from the whole-point-of-view as entropy and history that the passage has measure and direction. The units of energy which the physicist postulates for descriptive purposes are not apparently affected (barring the relativity effect) by their passage. They may enter into compounds in which new characteristics emerge, but their own character is not affected permanently, at any rate, by the combinations into which they enter. Real duration, in the organic and psychological sense of cumulative growth of the past into the present, is unknown in the physicist's

world. Cumulative duration depends upon the peculiar structure of living things, especially the highly organized living things. It is here that we have the duration of habit and memory. Time, as the real passage of events, is bound up with change, whether it be the emergence of something new or the dissolution of the old. The quality of the passage of events depends, not merely upon time and space, but upon the energy structure of the system involved. It is clear that the passage of events is prior to the spatializing of this passage in terms of chronological systems. The confusion of the temporal attribute of passage with the quantitative measurements of this passage has been one of the outstanding errors of philosophy.

In analyzing an activity system we must take account, not merely of the variables, but of the structure of the activity. It is this structure which gives meaning to the activity and which we try to state in a formula. In a world without structure, there could be no thought, and therefore no science. Without cosmic control there would be no measure, no quanta, and no patterned activity. It is true, as Kant pointed out so impressively, that if the mind had no structure we could not have knowledge. But it is equally true that if nature had no structure we could have no knowledge. Mind is an individual activity system in nature, and therefore can express nature. From the point of view of evolution, mental structure is a creative adaptation of life to the cosmos.

In activity systems the parts are sensitive, in determinate ways, to one another's presence in temporal and spatial relations. Otherwise there could be no community, but only isolated monads. This sensitiveness of the parts to one another and their mutual determination does not constitute an organism. An organism is a characteristic type of organization and assimilates, grows, reproduces, and interacts with the environment as only an organic type can do. But every system of activity is sensitive to the presence of other systems in determinate ways. Sensitiveness or awareness is always an attribute of activity systems; and since activity is universal, awareness must be universal. There is nothing inert in nature. Sensitiveness characterizes nature at all the levels of organization of energy. This is not animism. We must distinguish between awareness and mind. Mind is one type of activity system, bound up in this existence with a highly complex organism through which it functions. Mental activity systems also possess awareness; but, as with other activity systems, the awareness varies with the situations in nature. Awareness plays about the zone of activity, to borrow a metaphor from Bergson, and gets its color and significance from the activity system. We have now defined the five attributes of activity systems, viz. energy, space, time, awareness, and structure.

Qualities are functions or aspects of activity systems in their various actions, reactions, and interactions. There is no sense in speaking of a thing by itself as having properties, for properties are functional adjustments. There is no

such entity as a thing in itself. Everything that exists is interrelated in activity systems, and every activity system is sensitive to changes in its field, and every field is interrelated in a determinate way with other fields. The universe is itself a system of interrelated activities controlled by a total cosmic field. Qualities are the ways of things or the appearances of things in various contexts and under varying conditions. By thing I mean an individual activity system. The only clue we have to the nature of things is their way of acting. It is clear that the properties or qualities must vary with the situations in nature, since they are aspects or functions of determinate situations. Sense qualities involve certain organic specializations as part of the situation. But the organic specializations of end-organs and nervous system are as much part of the situation in nature as the stimulus. Sense qualities are physical emergent. But the discrimination of qualities, their abstraction as aspects of things, their meaning in the order of nature is due to mind and the social tradition. Not all properties are sense-properties. There is the immense variety of properties in the various contexts of nature where organisms do not figure – chemical properties, magnetic properties, etc., which are conditioned by the simpler systems involved and their interaction. These various functional relations in nature make a difference indirectly to our sense perception, i.e. we can watch the changes taking place in nature, or they may be noticeable only in their duration over periods of time, but in any case they are inferred to account for nature as we sense it.

Similarity and difference are not properties of nature except as we include mental reactions as part of nature. They belong to the second order, not the first order, of reality. They are the result of our conscious operations on the appearances of nature. Identity can have precise meaning only in the operations of measurement. Grouping things into classes on the basis of similarity is due to our subjective interest, though the result must be relevant to nature. The relevance has reference to the particular level of perception. Compare, for example, the discrimination of the expert with that of the novice or the discrimination through the microscope with that of the unaided senses. We may group various hues of red into one class or series on the basis of the subjective affinity of our responses to these incommensurable qualities. We may further group into a class of classes all disparate hues of color to distinguish them from the various qualities of grey; and we may group all the hues and grays into a more complex scheme because they all refer to the causal relations of certain energies in nature to the organ of sight. Clearly such grouping is a subjective affair and secondary to the primary appearances in the causal nexus of nature. Philosophers may hypostasize the classifications into essences or eternal objects, and talk about the participation of the individual appearances in the essences or the ingression of eternal objects into the individual events. Surely this is a trick of language. So-called essences like color do, indeed, subsist as abstractions in the realm of spirit and enjoy a

dubious eternity there, for they are linguistic fictions, the artifacts of mind. They do not exist in nature in the sense that properties do. They are affective responses, while properties are qualifications of certain causal situations in nature (including, in sense appearances, our organism). It is indifferent to the appearances in nature that they strike us as identical, similar, or different, though this may help us to sort them in convenient ways and so improve our adjustment to nature. This function of essences was first made clear by Locke. There is, however, objective structure in nature which mind must recognize; else there could be no approximation in the process of discovery. Between the energy systems of nature there are determinate exchanges. In these exchanges we try to discover constants which we can track through the exchanges. But the recent history of physics shows too clearly that these constants are pragmatic constants. The real structure of nature is for us a limit which we can at best hope to approximate. Even functional recurrence in the infra-microscopic realm of physics is probably statistical. Our reaction to nature, not nature, is stereotyped.

According to my own empirical realism we take account of reality as it is in our primary relations within nature. In our secondary or cognitive relations, we often err in our interpretations of appearances, but the appearances of which we take account are real. All the appearances of nature in various contexts are on a par, so far as existence is concerned. Our emphasis on some appearances as more important than others is due to our interests. For practical purposes our selection is different from our emphasis for aesthetic purposes. The spatial and temporal appearances, i.e. the appearances of distribution at various distances from us and the appearance of motion with reference to us, are as real as the appearances which we call qualities. Values are real appearances. But they exist only in contexts where desires are involved, for values are satisfactions. We rank values according to importance or worth, but this does not affect their existence. Spiritual qualities are as real as material qualities, and in human life are more important. By spiritual qualities I mean those which we recognize in our social intercourse, including the intercourse with the divine, wherever it is an experience and not just words. We recognize human selves as having an intrinsic meaning and value which we must respect, and which we demand that others respect in us. In other words, we regard selves as ends, and not merely as means. We recognize the striving for truth, morality, and beauty as the unique activity of rational beings. In other words, it is their function to create in accordance with conscious ideals, and not merely to enter blindly into the creative situations of nature. Ideals are creative energies in nature. The distinction between material qualities and spiritual qualities is primary, and not dependent upon our rationalization. We may rationalize the human individual into an organization of electricity, or we may regard him, as Aristotle did, as having an influx of cosmic creative reason, but the properties which we must recognize

in social relations are in any case the same. The activities are real, and they are for us *the* reality. We must deal differently with selves from the way we deal with material things. This conviction cannot be set aside by rationalization. On the contrary, reason, if it is fair, must take account of this difference in trying to piece together its experiences into a consistent whole.

If we conceive reality as activity systems, the great problem is the problem of organization. The organizations of activity, as we observe them, exist in various kinds, degrees, and ranks. These types are not absolute in the local evolution of which we are a part. They emerge in the process. The problem is: Why do they emerge? My belief is that they do not emerge by accident, but by virtue of the relation of our local field to the structure of the larger cosmic field and the genius of the whole. Activity systems maintain themselves by exchange with the environment. Matter cannot give rise to radiations of a certain type unless it is first charged by the patterned activity which it gives out. Hence in a self-maintaining cosmos there must be a constant process of give and take. This means that the types of organization are eternally incarnate in the cosmos, though the bearers vary, and, "like runners, hand over the torch of life."

In any local history, whether individual, social, or cosmic, the cycle runs its course because it is charged by patterned energy from the larger whole. But the response is not a mere repetition of the pattern communicated. The particular history responds to the stimulus in terms of its own structure and duration. The individual emerges as an act of cosmic genius in the appropriate conditions in nature. In the inorganic world there seems to be exact reproduction of patterns. Witness the similarity of the spectra of matter everywhere. But where there is cumulative duration, i.e. where the past is taken up into the history of the individual, the variation of response increases. The living organism becomes less and less dependent upon the immediate stimulus, and lives more and more with reference to the past and the future. This is evident wherever there is learning from experience, but especially so where there is imaginative memory and anticipation on the basis of memory. The unit of reality at any level is not the instant, but the dynamic whole-pattern of the individual with its duration. It is this whole-pattern which determines selection, assimilation, and response, whether on the chemical plane or the psychological plane.

If evolution is statable in terms of the organization of energy into greater complexity, there will always be a certain amount of relativity about what we call levels or critical steps in local evolution. The origin of living compounds marks for us a critical step of fundamental importance, though if we could have followed the stages in the evolution of nature we should probably have found it difficult to fix upon the critical moment. In some respects the evolution of the multicellular organism with its co-operative parts and forward-looking pattern is a more significant crisis than the simplest begin-

nings of life. What strikes me as the most momentous crisis is the appearance of creative reason, with its reflective analysis and synthesis. For this cannot be accounted for in terms of mere duration, however complicated. Creative reason cuts across the past and the present alike. It substitutes ideals or limits for custom. It marks the beginning of true freedom. Sensation, habit, memory, even the response to similar and kinds, may be routine. Creative thought marks a radical change in our response to nature and to man. It reconstructs experience in accordance with its own demands. Aristotle is right that here we connect with another order of reality, a spiritual order, the creative reason in the cosmos.

When we take the emergent point of view and follow the successive organizations of matter, through ever more beautiful complexities, it seems as though each later step in the series followed naturally from the preceding. We are especially inclined to invest matter, the lowliest emergent organization of energy, with greater and greater potencies. Mind itself becomes a function of matter, or at most a speculative hypothetical limit. Everything seems part of nature's routine. How different when we view the process from the point of view of creative spirit! In the communion of mind with mind, in language, art, and institutions, matter has merely instrumental significance. The supreme reality is the meeting of spirit with spirit in a unique synthesis with its emergent properties and values. As we view nature from the point of view of spirit, the process of evolution, i.e. the process of organization is seen as a process of spiritualization. As we follow the beauty of each stage of organization down to the atom and electron, the problem becomes to find matter. It is now matter which becomes a limit, the only significance of which is that it is the potential stuff for organization or spiritualization. The realm of matter and the realm of spirit are the two great realms, and it is the realm of spirit which overlaps. Here we have the great contrast. Matter spends its energy in radiation, spirit grows rich by expression. The more it spends the more it has. If it spends nothing, it dies. Therefore, it is more blessed to give than to receive. Matter is the realm of routine as contrasted with the free creativeness of spirit.

Matter is essentially a medium of exchange. It must become charged with patterned energy to give out patterned energy. Eventually, when the local expenditure exceeds the supply, the local matter goes the downward course. This does not mean absolute loss of energy. The energy which is expended here finds elsewhere a centre of reaction where the process of integration may start anew. This is implied in the conception of the cosmos as a going concern. The material energy is constant, but its distribution varies. In this redistribution, energy is communicated as patterns or whole forms; and these, in the adventures in space-time, give rise, in accordance with the local conditions, to a new cycle – as the communication of patterned energy in biological conception gives rise to a new generation of the type of the preceding or nearly

so, and as the patterned energy of society produces, in successive generations, greater or less conformity to the established type.

The cosmos, viewed as a whole, does not come into being or pass away. It is self-sustaining. It has a constant structure. Not only is its energy, viewed in the abstract, constant, but its levels or types of organization are constant, since energy is communicated as patterned energy. Evolution is a local process in which the material cycle runs its course, in unique response to the patterned energies communicated from part to part within the whole, under the guidance of the spirit of the whole. The patterned energies, which are communicated from more advanced systems, furnish the impetus to advance. The individual response, however, is due to the character of the individual system, and not merely to the impetus from outside. Hence there need not be individual repetition. This becomes increasingly true with the emergence of life and its unique duration. Over and above the routine of nature there is creative spirit, ever present in its own right and in its own kind – a unique realm of energy which exists, not by division but by unity, not by dissipation but by expression. This creative spirit gives meaning and order to nature's routine, and in the fullness of time incarnates itself into the flesh of mother earth to produce a new kingdom of order and value. Matter and spirit remain the two fundamentals. Of these, spirit gives organization, life, purpose, meaning, worth to the process. Matter furnishes the raw material and inertia. Transformed by spirit its random motion is standardized into patterns, and becomes meaningful and beautiful so far as its inertia permits. Without spirit, it is mere weather.

It is the tendency in present thought to emphasize science as the exclusive method of apprehending reality. Far be it from me to minimize science. It has vastly enlarged our conception of reality. But we have seen that at best science leaves us with abstract systems. It cannot, as science, give us back the unique reality of individual activity. Science must be rooted in the primitive convictions which furnish the background of thought and be supplemented by, and integrated into, the intuitions of concrete reason in moral, aesthetic, and religious activity. These intuitions must furnish the goal of scientific activity itself. It is in our moral, aesthetic, and religious experience that we grasp the individual significance of things and selves and the spirit of the whole. The world of values has its place in the scheme of the whole as well as the world of existence, and in the final analysis the two are inseparable. This must be true if we accept a spiritual control as the guiding field of activity. The world of values has its structure as well as the world of facts; and in our view of evolution the structure of value is the structure of fact. The structure of beauty is the structure of the cosmos, and science is really a pursuit of beauty, if the cosmos is dominated by spirit. In a broad sense the cosmic process is an aesthetic process, for the realization of pattern is aesthetic realization. Spirit increasingly dominates matter and gives soul to matter, until

emergent spirit wins its freedom and uses matter as its instrument in its expression of the ideal – the ultimate cosmic pattern, which in the imperfect process figures as a limit. There is, however, always the inertia of any level to the charge of a higher dominant pattern, and so we have the problem of maladjustment and evil.

The love of form, which is the individual inspiration of the scientist, the moralist, and the artist, points to the same objective order which in religion reveals itself as the great companion and enters into vital communion with those who are devoutly disposed. The genius of the cosmos creates in love and inspires the reciprocity of creative love. Being a free creator it seeks to bring to birth free creators. Its service is perfect freedom. It does not despise matter, but uses matter affectionately as the instrument of creativeness. But matter at best is a transient and imperfect embodiment of spirit. The creative genius who spiritualizes nature does not emerge in nature's cycles. It has its own individual life of infinite richness and value. It has its eternity in the life of spirit – in the ever-present cosmic spirit, which incarnates itself afresh, as the individual permits, in the cycles of matter, and in the continuity of emergent spirit within the economy of cosmic spirit. Here worth is the test of survival, and that survives which has sufficient prospective realization, in other words, which can enter into the freedom of creative spirit.

In a world in which spirit lives and works, the free realization of the category of worth, as set by the spirit of the whole, is immortality. But in a pluralistic world of interaction and freedom there may be damnation as well as salvation. We determine what the world shall be for us in the world of values. Whether our individual life is worth living or not, whether the pessimistic or optimistic outlook is justified, whether we are free creators, or creatures of circumstance, whether damnation or salvation shall be a fact, as far as we individually are concerned, is a venture of faith. The structure of value is eternal, but our participation in it lies in our own control. To choose freely to realize, in our individual lives, the beauty of spirit is the great affirmation; to refuse to do so is the great negation.

Time and Reality, Psychological Review Monograph Series, 1904.
Truth and Reality (Macmillan). 1911.
A Realistic Universe (Macmillan). 1916.
Cosmic Evolution (Macmillan). 1925.
Studies in Social Theory in the *American Journal of Sociology*, 1913, 1914, 1915, 1917, 1921, and in the *International Journal of Ethics*, 1914, 1919, besides articles in various journals, which have been incorporated in part or in a revised form in the above books. These have been indicated in the prefaces.

FUNCTIONAL REALISM

John Elof Boodin. "Functional Realism." *Philosophical Review* 43.2 (March 1934): 147–178.

The presidential address to the Pacific Division of the American Philosophical Association at the University of California at Los Angeles, December 29, 1933.

The American realists[1] have grouped all types of realism into two classes: "naïve" and "critical." Both titles are misnomers, since the "naive realism" of philosophers is sophisticated and "critical realism" is based on dogmatic assumptions. But they serve to indicate two different attitudes to our knowledge of nature. Because of the wide publicity which these two attitudes have had in America, a third fundamental type which I shall call "functional realism"[2] has been neglected though its lineage goes back to Protagoras. It is this type which I shall try to explain and defend in this paper.

It is not my purpose in this paper to exhibit the variety of realisms, which are only limited by ingenuity in coining phrases for various permutations. I am concerned with the underlying principles. From this point of view there seem to be three fundamental types and the remainder can be considered as hybrids or variations. (1) The type which holds that the qualities and the relations which we sense exist in objective nature independently of the percipient organism, just as we perceive them. This is naïve or direct realism in the strict sense. (2) The type which holds that the qualities and relations which we sense are mostly due to the percipient organism and do not exist in objective nature as we perceive them. This would be critical realism in the strict sense. (3) The type which holds that the qualities and relations which we perceive are functions of objective nature and the percipient organism in perspective relation to one another. This type I call functional realism.

[1] British realists, such as G. E. Moore, C. D. Broad, H. H. Price and others, have made a more extensive analysis of types. But I am concerned with underlying principles rather than with variety of types.

[2] For the author's previous statements see *Truth and Reality* (1911) Chs. xiv and xv; an article "Knowing Things" in *The Philosophical Review*, 1912; expanded in Chapters 5 and 6 in *A Realistic Universe*, 1916 (revised 1931); and Chapter 7 ("Space-Time Perspectives") of *Cosmic Evolution*, 1925.

Naïve and critical realism have one fundamental assumption in common. They both assume that to say that substances and qualities exist independently of the environment has a meaning. They make, at the outset, a bifurcation of thing and environment as though they were only externally related. They postulate things in themselves with properties in themselves. This postulate rests on an antiquated science. According to the old scientific conception – which goes back to Leucippus and Democritus – an atom would remain the same though everything else were destroyed. Its character is intrinsic to itself. This postulate leads to opposite results in naïve and in critical realism. The naïve realist implies that the percipient is neutral in his awareness of the external world and therefore he perceives the qualities and relations in external nature as they are in themselves. He fancies himself to be an angel. The critical realist is aware of being in the flesh and believes that the percipient organism, by a characteristic action of its own, fakes the properties of the external environment and therefore he cannot get to the properties of the external substance as they are in themselves. But both the naïve and the critical realist assume that there are things in themselves with properties in themselves. About the relation of these properties to the thing in itself neither troubles himself. And the reason for this is that both of them are part of the Aristotelian tradition, *viz.*, that properties inhere in substances. Aristotle supposed that it is possible analytically to abstract these properties from the substance until you get to the underlying indeterminate substrate – like peeling off the layers of an onion, and, as in the latter case, nothing remains.

As opposed to the assumption of things in themselves with properties in themselves, functional realism holds in common with present science that the bifurcation of thing and environment is vicious, that things exist only in fields, in mutuality with other things, and that they have properties only in their dynamic interrelations. We may illustrate this conception with the property of weight, one of the most fundamental properties of the physical world. Democritus and Plato thought that weight is due to the amount of matter. Since the atom is supposed to be a plenum, *i.e.*, absolutely full of matter, the difference in the weight of atoms must be due to difference in size. Weight was supposed to be an absolute property and in no way affected by the environment of the atom. Newton discovered that it is functional, that it depends upon the relation of matter to its environment. Without an environment of matter there would be no meaning to saying that an atom has weight. Unfortunately, Newton did not see the bearing of this discovery upon substance and property generally. If he had, the course of modern science and of modern philosophy would have been different. Philosophy would not have been haunted by the ghost of things in themselves and modern naïve realism and critical realism would have died unborn.

Since properties are dynamic relations of energies involving time and space and are therefore directional (or, as mathematicians would say, have the

vector-character) within the dynamic network of nature, we may speak of them as perspective relations. A configuration of energy, which we select as a frame of reference, exists as such a configuration and has the character it has by virtue of taking account, in its own way (because of its history and organization), of the environmental configurations of energy in specific space and time relations within the cosmic situation. This does not mean that the individual configuration does not count. The relation of mutualness of parts would have no significance unless the parts contributed to the relation. Nature consists of a great variety of individual systems of energy with their individual history, organization, inertia and "aptness" (as Locke would say) to participate in the cosmic matrix. Science indicates that there is an element of indeterminacy in the behavior of nature, and therefore an element of uncertainty in the prediction of individual reactions, though if we take individuals in the mass we may have statistical prediction. But what I wish to emphasize is that no individual organization, be it an atom or a human personality, lives to itself or dies to itself, but all are members, one of another, and of the whole cosmic community, with its super-individual control.

If we speak of the dynamic relations in nature as perspectives, we must understand that the perspectives are integral to reality and not merely incidental, as those who cling to substances in themselves with properties in themselves are apt to suppose. "In the perspectives of experience," says Santayana, "I cannot, except in these very perspectives, reach the terms which they posit as self-existent in order to see whether my perspectives were rightly drawn. I am in the region of belief mediated by symbols, in the region of animal faith."[3] If one held, as Santayana does, to "self-existent terms," one certainly would be in a dilemma and it is doubtful whether even "animal faith" would help. But self-existent terms are a fiction of an antiquated science. "A thing is what it does," as St. Thomas Aquinas and Lotze truly affirmed. And a thing does not do anything by itself. It exists and has properties only when it reacts with something. It is itself only as it is mutual, as Hegel might say. Its properties are due to what it acts on as well as to itself. The physicist has learned that he cannot say what an electron is when it does not act. Its character of individual particle is very likely due to the encounter with radiation or another electron. All we know about it is what it is when it acts. Anything else is a *post facto* projection. And that is true of everything else. To act implies space and time. It implies direction of action from a certain place and time to a certain place and time. We cannot say *a priori* that the direction must be straight. That depends upon the field in which the action takes place. The direction may be curved. But we can say that all action is perspective from some configuration to some configuration of energy in time and space. What we consider as the terminus of the action is

[3] *Scepticism and Animal Faith*, p. 115.

as much a part of it as what we call the initiation, and the two are reciprocal. There is not in nature the relation of active and passive. Everything in nature is active. What we consider as agent or as re-agent depends upon our interest. Nature knows no such distinction. Perspectives in nature are nature in action and nature exists only in action. But one perspective cannot give the whole of reality. Nature exists in an indefinite number of perspectives in the plurality of interacting systems of energy in nature. There is also an indefinite number of possible perspectives. Possible perspectives of action are perspectives which may occur when certain conditions shall be present which are not now present. I see the salt granules. That is an actual perspective. But I can also put salt on the tongue and get its saline taste. That is a possible perspective relation. Since I have experienced this saline reaction at various times, I consider it as one of the possible properties of salt.

We may call the reactions of nature, of which we must take account as immediate data, *primary perspectives* as contrasted with our judgments of nature which we may call *secondary perspectives*. These two types of perspectives vary independently of one another, the former with the conditions in nature and independently of my interest, the latter with my psychological history. We do not create the primary perspectives by taking account of them. The salt produces a saline reaction on my tongue, whether I want salt or not. I may mistake it for sugar, but it still tastes saline. Whether I want it or what my judgments are about it depends upon the psychological situation which in turn is bound up with my past experience. The primary perspectives are objective to my secondary perspectives. The secondary perspectives are subjective, but that does not mean that they are unreal. They are part of nature as truly as the primary perspectives. They may be more important to my conduct than the primary perspectives. It may be vastly more important to me what a person's subjective point of view is than what he perceives as objective in nature. And it may be more difficult to change it than to change the configuration of the landscape. Subjective points of view are energy-perspectives of which we must take account.

While we may distinguish for purposes of analysis between primary and secondary perspectives, they are not separated in our life in nature. In the adult perception of philosophers, conceptual elements, including language, enter into their perceptions of nature. The conceptual elements permeate the perspectives of immediate experiencing, and become identified with the situation as sensed. This accounts for our perception of definite things. We do not sense *things*, though from philosophers' talk about pens and tables one would suppose that we do. Things are the result of interest and conceptual interpretation. A pen or a table is a group of perspectives in nature that fulfils a definite purpose. A table is not "given," liberal though philosophers are with the "given." If "given" has any legitimate meaning, it is that we can abstract an aspect of nature and use it as a datum or problem for investigation.

Material things are not given any more than spiritual things. Both are interpretations of the aspects of nature. Both involve a high grade of social consciousness with the fixations of meanings in language. History shows that we are only too apt to introduce our evaluations into the primary perspectives of nature. Such an evaluation is that of primary and secondary qualities. This distinction is irrelevant to nature as sensed. It is the result of an evaluation of nature for our purposes – descriptive, practical, esthetic. So is the distinction of appearance and reality. The experience of nature on the level of philosophers is shot through with judgments and evaluations which philosophers too often confound with the "given." On the reflective level there can be no "raw experience." To have such experience of nature we should have to return to early infancy. For reflective human nature perceiving is conceiving. But we must see to it that the conceptual interpretation is relevant and adequate to nature as experienced. The conceptualizing of our immediate experience, no doubt, enriches our understanding and enjoyment; and it makes possible the control of nature. But we should not confuse the conceptual elements with our immediate perception.

We must distinguish between the qualitative perspectives of nature and the spatial and temporal perspectives in the causal matrix of nature. The failure to make such a distinction has resulted in much confusion in our epistemological theories. Qualitative perspectives are nature actualized in the specific situations in which we sense and feel nature. They are nature as immediately lived. They include the causal conditions of nature. For purposes of prediction and control we analyze the causal situation into factors and conceive our qualitative world as emerging from these. But the causal factors must not be taken in the abstract. They are projections by the mind to account for the qualitative world and must be relevant thereto. They are real only as actualized in that world. Nature is what it reveals itself as being in our qualitative experience, though it is not exhausted therein. In nature are an indefinite variety of qualitative occasions of which human nature is not a part.

Our qualitative experience carries its own credentials. Primitive man lived this qualitative world as truly as we, though he was ignorant of the causal conditions, and we know but little of them. Like primitive man we eat what agrees with us and depend upon nature to do the digesting. The world of qualitative experience is rich. It includes not only the sense-aspects which we refer to external things, but also our feelings, our values, which reveal nature under certain conditions as truly as do the sense-qualities which we use as descriptive of nature. For the organism, with its interactions, is part of nature as much as the external world. Nature is pleasant or unpleasant as truly as it is extended and colored.

The qualitative experience of nature has its own completeness. Its qualitative aspects cannot be eked out by reference to the causal conditions of nature, but only by reference to one another. The qualitative acquaintance

with nature through one sense is eked out by qualitative experiences through other senses, and external sense-experience is eked out with affective and motor experience. Man could not have lived if a causal knowledge of the world had been a requisite for his qualitative experience. He has adjusted himself to his world, first of all, on the basis of his qualitative experience of his reactions to nature. He has been guided in his use of the environment by the qualities of things as he has sensed them and the felt satisfactions and dissatisfactions which things have produced in his experience of them. The values of things have been of no less importance than the descriptive qualities. In fact, the former have been practically of prior importance, though not more real than the latter. In this qualitative world the organism has oriented itself to things spatially and temporally, as the magnet orients itself to the lodestone and as the plant orients itself to light. Like the magnet and the plant, the human organism exists in the spatial and temporal field of nature. It does not, any more than the magnet or the plant, require "animal faith," as Santayana supposes. Nature is activity and activity is spatial and temporal. There is no mysticism in this except in a false philosophy. Because different observers can have the same organic perspectives in nature, the qualitative aspects which they investigate become integrable and, therefore, communicable as between different observers. Different organic perspectives, whether for one observer or as between observers, are not integrable if the qualitative difference can be distinguished, though they may practically be integrable, *i.e.*., the difference may not matter for the purpose.

Qualitative experience has its own temporal and spatial perspectives. Man's kinesthetic sensations have enabled him to adjust himself by organic habits to the distances of things and the motions of things, even before he learned to reduce his qualitative world to quantitative measures, though these have added greatly to his effectiveness. The quantitative measures are themselves part of the qualitative world. We measure sensible magnitudes by other sensible magnitudes which we select as our units. We do not measure magnitudes in our brain, however abstract we may become in our calculation and however convenient it may be to substitute numbers for the sensible magnitudes. The scientist may fool himself into thinking that he is just dealing with abstract counters or "pointer readings," but these would have no meaning except for the concrete world from which they are derived. Even the magnitudes which are far below our sense-perception must be measured indirectly in some way with reference to scales which we can perceive, or we should have no evidence.

Through its kinesthetic sensations from joints, muscles and tendons the organism has the qualitative experiences of motion, resistance and strain in its life in nature. It is from these humble organic sensations (together with the diffuse sensations from our autonomous system) that we get our first-hand realization of the "go" of nature. And however abstract our mathematical and

physical description of the "go" of nature may become, it has its starting point in these specific organic sensations, without which, as Poincaré truly saw, we should have no mathematics or physics. Without the sensations of movement we should have no geometry and without these and the sensations of strain and resistance we should have no physics, though it does not follow that we can transfer our macroscopic experience of pushing and pulling to the minute conditions of nature, whether within or outside the organism, as the old physics did. Even our most ideal activity, with its consciousness of intention or direction, is dependent upon these humble organic sensations for its consciousness of realization. For man is an organism and not a ghost; and his activity, whether of the primary or secondary level, is the activity of an organism.

It is evident that the human organism requires a variety of experiences – visual, auditory, kinesthetic, affective, etc., for its acquaintance with nature, but these are integrated into the life of the organism, as a whole, to further its will to live. It is a vicious abstraction to conceive of man as just a sensory being in his life in nature. The externally referent sensory life of man is bound up with his affective and his motor life. If his sensory life determines his affective and his motor life, these no less determine the effectiveness of his sensory life. There can be no impression without expression. What we perceive is conditioned not only by what we sense, but by what we feel and by the motor adjustment of the organism, as Brown[4] has so well shown. We cannot understand the life of the organism in nature unless we view it as an integral whole – sensory, affective and motor – in the hierarchy of organization which is involved. Of this hierarchy we are not immediately aware. It belongs to the causal conditions of nature which we postulate in order to understand the life of nature. But this organization figures none the less in the actuality of man's life in nature.

The confusion of the immediately experienced qualitative perspectives of .nature with its inferred, problematic, causal factors has dogged both the direct and the critical realists. When the direct realist says that the light-rays are colored independently of our organic reaction, he has attributed to one part of the causal nexus what is the function of the whole, including the organism. It is as though he should say that because H_2O is wet hydrogen must be wet. Sir James Jeans has shown that when we look at the blue sky or the sunset through a long narrow tube, we perceive no color but only splotches of grey. The environing parts of the retina must be stimulated to get the color effect. But further than that, the sensory surface itself would not exist except for the sensing. We could not by getting nearer the perceived object get the object

[4] See Harold Chapman Brown's presidential address for 1932, "Mind: An Event in Physical Nature," *The Philosophical Review*, XLII, pp. 130–155. The phrase, "physical nature," shows the author's prejudice.

which the physicist infers from his more refined instruments, physical and conceptual. It is of no interest to us that the direct realists have sometimes lost their nerve and have attributed some of the sense-qualities, such as those of taste and smell, to the action of the organism, since we hold that all the sense-qualities are compound functions, involving stimulus and organic conditions. Olfactory qualities are no more or less organic than color qualities. Nor is it of any interest to us that some realists, like Thomas Reid and S. Alexander, have postulated a special faculty of intuition for the so-called primary qualities. All perceived qualities are alike sensory experiences of nature.

The critical realists have been no less confused as regards the qualitative field of perception and the causal conditions. They too have held that we must get to the physical agitations at the source or in the immediate vicinity of the stimulating energies in nature in order to get the real character of the sensed object. But they have been troubled by the fact that their organisms are not neutral but react in characteristic ways. If naïve realists imagine that they are angels, the critical realists try to imagine what the world would be if they were angels. We cannot examine the variety of ways in which the critical realists have conceived the relation of the percipient organism to external nature. Some, following Locke, have thought that the primary qualities get through somehow and that we perceive them as they really are in nature or at any rate very like what they are. But how can we know? If we compare the macroscopic world of our perception with the postulated microscopic world of the mathematical physicist, it is difficult to see what the resemblance can mean. Other critical realists have maintained that we perceive no qualities as they are in nature, but only the mathematical relations, forgetting that mathematical activity is certainly as characteristic of the percipient organism as the sensory activity. If they mean that we perceive geometrical configurations in the field of immediate qualitative experience that is true. But these are certainly as organically conditioned as the qualitative aspects of the field. Moreover, psychology has shown that the geometrical configurations are marked off by the qualitative aspects. Light and grey shades are particularly effective in marking off contours. The color aspects are not so effective, as they tend to blend. But what these critical realists mean is presumably that the geometrical contours to which they give a peculiarly objective status are identical with or at least resemble the contours of the external physical field in the absence of the percipient organism – if he only could get to them. Alas! If only the critical realist had no eyes he might see. As it is, the contours he perceives are certainly due to the selective reaction of the organism. Without the organic reaction there would be no continuous surfaces in nature. In short, the critical realist has made the same mistake as the direct realist in attributing to one set of causal conditions in nature, *viz.* the physical, what is a compound function or emergent of the physical and the organic conditions in conjunction.

Other critical realists go the whole length and maintain that both the qualitative characters and the mathematical relations are contributed by the percipient organism. This was the position of Kant and seems to be the position of Whitehead. This means universal agnosticism as regards the knowledge of nature and is the logical result of critical realism. This Kant clearly saw and was properly puzzled over the fact that science discovers empirical laws in nature. As I understand Whitehead, the organism first projects a geometrical schema and then invests it with the sensory qualities which it fabricates. He admits external stimulus but regards this as "irrelevant." But if the rhythm and intensity of the external stimulus show a correlation with the sensed quality it is difficult to see how they can be irrelevant. It is true that the organic condition is also a factor, and this may produce variation in quality independently of the external stimulus. For example, towards twilight, when the intensity of light is weak, the organism does not respond to wave-length with characteristic color discrimination and the environment is murked in grey. But with dual conditions we should expect variation in quality with the variation of either condition. Presumably what Whitehead has in mind is that when an external energy, such as light, acts upon another kind of instrument, such as an interferometer, it reveals itself as frequencies and not as color. But we should expect light to reveal different characters in acting upon different instruments. When light acts upon a normal retina under normal daylight conditions, it is colored. Color is light when actualized in the retina. As Aristotle put it, when light does not act upon the eye it is only potentially color but when it is actualized in the eye it is color and then the world is colored. Of course this is only one way in which light may be actualized. It may also be actualized in the interferometer and then it is frequencies. Is not frequency an emergent property as much as color? What can frequency mean apart from proper instruments of reaction?

Whitehead, however, attributes little importance to sense-quality. Instead, he stresses feeling. His language of feeling is as fluctuating as the feelings. He sometimes uses feeling in the psychological sense of feeling tone. In this sense, it is a fusion of a large mass of organic sensations, especially from the autonomous system. This is an emergent fact as much as the sense-qualities which we use to characterize external things. While feelings are an important revelation of our life in nature, they are certainly not less organic than the more specific sense-qualities. Together with the specific sense-qualities, the feelings constitute the immediate awareness of our life in nature. They are more massive and in that sense richer than the specific sense-qualities. But that is no reason for putting them on a different metaphysical basis. Sometimes Whitehead uses feeling for our whole immediate awareness of nature. This immediate awareness he calls prehension, as contrasted with apprehension. Prehension suggests active seizure; and feeling, instead of being an emergent, becomes an efficient cause in nature. As all nature is organic for Whitehead,

feeling becomes *the* efficient causation in nature. And since reality is conceived as dynamic, feeling becomes reality, and Whitehead is brought by his own route to the mysticism of Bradley. Feeling, as one type of the emergent actualization of nature – the florescence of life's activity – becomes the whole of reality. Such ambiguity will give the philosophers much material out of which they can make a living and will no doubt be perpetuated.

Presumably the critical realists consider themselves critical because they base their arguments upon physiology. They demonstrate, if nothing else, Pope's aphorism, "A little learning is a dangerous thing." We know little of the physiological conditions of sense-experience. We do not know what are the respective contributions of sense-organs, intermediate neural centers, and the cerebrum. They all have a share, no doubt, in the conditioning of our qualitative experience. The past emphasis has been upon the sense-organs. But the stimulation of separate nerve-fibers could not furnish the condition of the variation in intensity, since separate fibers act by the all-or-none method. The variation must be due, somehow, to the stimulation of a number of fibers and must be a resultant in the neural centers. The cortex, it seems, may become charged with vibrations which originated through connection with the environment. Not only can a blow on the head make us see light (though confusedly) but visual and other experience can be initiated from within, as shown by memory-images, not to speak of hallucinations. Direct stimulation of the upper temporal convolution can produce the consciousness of sound and even different pitches of sound (though there may be a reflex effect to the ear and back by way of the centrifugal sensory arc[5]). What seems clear is that the sense-organs and the nervous system under normal conditions act as a unit, and that the sensory quality as perceived is an emergent from the total action of external energy, sense-organ and neural hierarchy. The percipient organism does not sense a stone as a grey patch on its own retina (as Whitehead supposes), though it may sense a patch on somebody else's retina. Seeing is first of all a photochemical process and it involves the hierarchy of neural centers as well as the retina. For spatial localization in two or three dimensions there must be a schema of the cortex, as Head has shown. When the cortex is badly disintegrated, whether from disease or accident, the patient loses his epicritic sensibility, *i.e.* he can no longer distinguish locality, intensity and rhythm. But neither can we regard a percept as a patch in the cortex, as Bertrand Russell seems to think. It could not be revealed by microscopes. Russell appears to have confused the causal conditions of sensing with the emergent fact of sensing. We may have external perceptions of the brain, even of the living brain through an operation of trepanning. We might even see our own brain in such an operation with properly placed mirrors and we might

[5] See the author's *Cosmic Evolution* (1925), p. 151.

conceivably touch it with our fingers, but that is a very different sort of functioning from the brain *perceiving* its own sense aspects.

All primary perspectives in nature are real. There can be no question of their existence, whether it is the perspectives in the physical and chemical transactions outside of the organism or the sensory perspectives in the interaction of the organism with its physical environment. There are no illusions in the primary perspectives of nature. All illusions are due to judgments, whether it be the implied judgments on the level of "conditioned responses" with which the behaviorist deals, or the articulate judgments in which the philosopher is interested, or the gradations between these levels. The challenge of the reality of our immediate sense-perspectives on the ground of illusions is based upon a confusion of secondary factors in experience with primary factors. That a stick appears bent when seen in the water is not an illusion on the primary level. The appearance of bentness is a true perspective, physically and organically, in that situation in nature. It becomes an illusion only when we judge that because a stick appears straight in the air, it should have the characteristic of straightness when seen in the medium of water, or when we demand that because the visual appearance of straightness in the air correlates with the tactual appearance of straightness, therefore the tactual and visual appearances should be correlated when the stick is seen in the medium of water. But there is no *a priori* reason why appearances in different sense-perspectives should have a constant correlation. Things with a pleasant taste are generally correlated with pleasant organic effects in the alimentary system, but when they give us a stomach-ache we do not call that an illusion. Images in mirrors have been called illusions. But there is no illusion in the primary perspective. The reflection of light in a mirror is a true physical perspective and the sensing of the physical transaction is a true organic perspective. It is only when some one judges that the image in the mirror is the thing itself, as perhaps a young dog or a young child or a critical realist might do on the basis of resemblance, that there is an illusion. But there is no illusion either in the physical perspective of refraction and reflection or in the organic sensing of the physical situation. It is only because we are prone to identify the secondary perspectives, which are the result of the psychological set and history of the observer, with the primary perspectives of sense, that we attribute such illusions to the latter. I do not experience the image in a mirror as an illusion. Functional realism accepts the veridicalness of direct experience. Of the causal conditions of direct experience our knowledge is fragmentary indeed. But our ignorance of the conditions does not invalidate our direct experience.

Since Berkeley's brilliant analysis it should not be necessary to refute the mistaken notion that some sense-qualities have a privileged character, *viz.* that some appearances of shapes or sizes or motions are true while others are false. As he pointed out, we can have no standard for sense-qualities except other sense-qualities. Some philosophers are still simple enough to imagine that

some sense-appearances are true to the physical character of the world, independently of our organic reaction, but microphysics would not give them any aid. It is convenient for certain purposes to select a certain perspective as our standard, but that has nothing to do with the question of reality. Few, I imagine, even among philosophers, would be naïve enough to say that the color seen in daylight is true and that seen in electric light an illusion. It is plain enough that we must select the conditions in nature for which we want a certain color, as any woman would do.

It has been charged against our immediate qualitative experience that it is fleeting – that it is always becoming and never really is and therefore cannot be the basis of truth. This prejudice is as old as Plato. When Hume introspected he could find nothing but feelings and ideas succeeding one another with incredible rapidity, and modern philosophy has generally been introspective. William James adopted from some obscure writer the fiction of "the specious present." The moment of conscious experience was supposed to be a sort of saddleback, including a top or zone of clearness (as Titchener called it) and descending to the vanishing point at either end, one end being the vanishing into the immediate past and the other the emerging of the immediate future. The whole moment was supposed to occupy only a fraction of a second, though it might possibly be stretched to two or three seconds. This fiction has found great favor with philosophers. With psychologists the method of introspection has become suspect or is used cautiously. Behavioristic psychology deals with responses and Gestalt psychology with direct experience. In neither case does "the specious present" have any relevance. The specious present was based presumably upon attention. Attending introspectively is a difficult and notoriously uncertain undertaking. We must have objective tests. Now it is found when we try to attend to a black dot on a white background, or when we attend to minimal stimuli – a very faint light, sound, pressure – that attention acts in a rhythmic way. The object goes out and reappears again. The reason for this is obscure. We know that single nerve-fibers quickly become fatigued and as quickly recover again. The rhythm may be due to the narrow physiological base of the sense-perception. At any rate when the field of direct experience has complexity we can attend to an object for a considerable time. It does not seem to go out. And normally we do not glare at a dot but at a field. We may test the limits of attention temporally by the number of successive sounds of which we can take account without using recall by memory. The number varies with groupings; we can take account of as many limited groups as individual sounds. But attention shows the same limitation in simultaneous exposures. We only perceive, in the sense of being able to recall, a small number of events – dots or numbers or words in an exposed field – but we can recall about an equal number of groups within a limited space. There is no reason to suppose that the limit or the rhythm of attention is the same as the limits or rhythms

of sensory experience. We are vaguely conscious of a field of varying complexity and varying relations though we are attending to only a small part, and the gestalt psychologists have shown that the total field is effective in determining the character of that part to which we are attending. The fiction of the specious present seems to serve no useful purpose in psychology and I do not see why it should be kept alive in metaphysics. Attention is the spearhead of action and has great executive importance, but no great metaphysical significance.

Our experience of nature is not a single-file succession of events, but a field with its own extensity and duration, within which we can distinguish parts with varying extensity and duration. The temporal, spatial and causal relations of this enjoyed qualitative field are not added to the qualitative aspects of the field by the mind. They are intrinsic to the field; the qualitative experience is spatial, temporal, causal. The chimpanzee which bit angrily at the branch on the stick, with which it was trying to reach the bananas on the other side of the bars, had the immediate experience of spatial, temporal and causal relations in its qualitative reactions in nature, though it also had the insight to attend to those relations and not merely fumble by mechanical trial and error. It had the consciousness, in its discriminative responsiveness, of its organism as an active factor in nature. If the relations were linguistic abstractions, such as Bradley postulates, we should indeed be unable to bring the *disjecta membra* of our experience together and should in despair have to fall back on mysticism. But relations are intrinsic to our perspective qualitative experience of nature. This experience is temporal, spatial, causal, with its cumulative organic significance. As a secondary operation upon this matrix of immediate experience, the organism can distinguish similarities and differences in the qualitative field and establish new groupings of sorts or kinds. In recognizing sameness in its reaction it can create "essences" or universals which are derivative from qualitative experience and do not hover in a world of their own.

I see no reason, moreover, to suppose that we perceive past, present and future moments of time.[6] Our direct experience, no doubt, has duration, extensity, groupings, both simultaneous and successive, and relations of nearer and farther, spatially and temporally. But such characters are aspects of direct experience. We may, as a result of our practical interests, have the feeling of goneness of that which has disappeared and of expectancy, which may be merely organic alertness. But the schema of past, present, and future is an ideal construction on the part of high-grade minds. And the quantifying of the direct experience of duration into moments – seconds, minutes, hours,

[6] For the discussion of past, present and future see the author's *Time and Reality* (1904) Ch. v and *A Realistic Universe* (1916, 1931) Chs. xiv and xv. *Cp*. A. N. Whitehead's *Adventures of Ideas* (1933) Ch. xii.

days, years – is certainly as artificial as the quantifying of the direct experience of extensity into units – feet, yards, miles or whatever may be the nomenclature. The schema of past, present, and future and the schema of moments are the results of operations upon our direct experience in the service of conceptual interests. To speak of the handing over of the past or the thrust into the future is plainly an inversion. Our memory makes the consciousness of the past and our expectancy makes the consciousness of the future. These are dimensions which the mind creates, they are not forms which are given to it. More fundamental than our ideal constructions of past- ness and futurity are the transformations in nature which, on the one hand, condense into the cumulative organic structures which enable us to re-live in a new situation occasions which we are conscious of having previously experienced, and, on the other hand, emerge as novelty on the background of the present field of experience.

What I wish to emphasize is that we derive our conception of constancy as well as our conception of change from our direct qualitative experience. Within the field of experience there is varying change and varying constancy. Various parts of the experienced field, whether we view it objectively or subjectively, have different durations. Some are fleeting, others endure indefinitely. Sense-qualities in the objective field have a high degree of constancy. Our feelings are supposed to be particularly fleeting, but some endure and become likes and dislikes. Our emotions, while not a matter of a fraction of a second, cannot stay at high pitch indefinitely, but as moods they may have a long duration, as sentiments they may continue indefinitely. It is the constancy of our qualitative experience of nature which leads us to seek for constancy of conditions to explain it. We invent "eternal objects" of matter because of the constancy of the qualitative sense-aspects which we group as material. The qualitative experience is constant within our epoch of nature, but the "eternal objects" have proved very mortal the last few years. Let us give direct experience its due. It is from direct experience that we must derive our concepts, and our concepts are valid only so far as they are relevant to our direct experience. If our qualitative experience which we call water were always perishing and never the same, we should not think of discovering constant elements to explain it. As a matter of history the early conceptions of elements were those of qualities – the wet and the dry, the hot and the cold, and the light and the heavy.

The veridicalness of our sensory information of nature has been challenged on the score that the sensed quality or group of qualities is in a different time and place from the thing perceived. It has been pointed out that if the thing is away from the organism it takes time for the excitement in the things to travel in order to reach the percipient. We cannot say, therefore, that we perceive Sirius, for light is supposed to require eight years to reach our earth from Sirius, and Sirius may have exploded in the meantime. Even when we

sense parts of our own organism, it takes time for the neural excitement to reach the cerebrum; and it even takes time for excitement in one part of the cerebrum to reach another part. According to Whitehead the organism is in the past in perception – past to the soul, which he does not define. The conception of transmission seems to make impossible the consciousness of direct acquaintance with nature which we all feel that we have. We are here face to face with one of the fundamental dilemmas in our conception of nature. Our immediate experience is convincing. We feel in immediate community with nature, including the distant nebulae revealed by means of the telescope and spectroscope. But how can this be, if the excitement, which is part of the causal condition of our experience, takes time to travel? Instead of living in the expansiveness of nature, as we normally feel and believe that we do, we seem on the basis of current philosophy to live only in the cortex and even a patch of the cortex. Must we abandon the evidence of direct experience and instinctive belief? This is doubtless the greatest wave of objection that we are obliged to breast. What Hercules can we summon to get us out of this predicament?

There is another principle which has been overlooked by philosophers, namely, the principle of cosmic immanence. This principle first struck the scientist's attention in his investigation of the minute structure of nature. The Rutherford model of the atom conceived an atom as a planetary system with a central nucleus and with electrons moving around it in various orbits. Bohr found that when there is radiation from an atom, an electron must shift from one spatial orbit to another – from an inner to an outer orbit. The scandal was that this shift is instantaneous. But if electrons are particles of electricity, the shift must take time. Science was confronted with a critical instance of absolute simultaneity in nature, and if such simultaneity can exist on a small scale, it can exist on a large scale. A new conception of the electron was called for and this resulted in the wave-mechanics of Schrödinger. As a wave an electron may be immanent in various orbits, and two or more electrons may be immanent in the same orbit, though not functioning in the same way. It would be too long and too difficult a task to unravel the new quantum physics. But we are here concerned only with the principle of cosmic immanence. Schrödinger's electron pervades all space in its three dimensions, though with decreasing intensity. The universe is an interlacing of waves. Everything is immanent in everything else. But energy becomes kinetic only when there are "beats" and a new harmonic must be established. It cannot be said that the wave-conception has crowded out the particle-conception. In direct action electrons seem to bombard as though they were particles. Many physicists regard the wave-conception as the more fundamental, but the evidence seems to require both. The same duality of wave and particle reveals itself in electronic matter as had previously been shown to exist in radiant energy, and the conviction is growing that electronic matter is

ultimately a condensation of radiation. It has been held for some time that matter spends itself in the stars as radiation, and there seems to be recent evidence from the physical laboratories that radiation may become condensed into electronic matter.

I believe that the principle of cosmic immanence is the Hercules which can rescue direct experience from the onslaughts of epistemologists. Let us transfer the scene to physiology. Increasing evidence shows that the brain does not act merely as a collection of neurons but also as a field, *i.e.*, as a unit. The structure of the whole brain is involved (as shown in experiments in re-education and elsewhere) in perception, in the learning process, in remembering and thinking. That means that in some respects the parts of the brain are immanent in the whole and the whole brain is immanent in the parts. Biochemists, led by Claude Bernard, have come to the conclusion that in some respects the organism acts as a whole. This has been brought out strikingly in the researches of J. S. Haldane on breathing, and L. J. Henderson on the circulation of the blood. That the cerebrum is immanent in the lower neural centers and in the sense-organs is shown by the epicritic control and dominance which it exercises upon the processes of sensing and reaction. Without this control the human organism, at any rate, reverts to sensing and action of the all-or-none type. We may of course turn the situation round and say that the sense-organs, lower neural centers, glands, are immanent in the cerebrum.

Let us now extend the conception of immanence to cosmic proportions, and we may say that in some real respects the human organism is immanent in the cosmos and the whole cosmos is immanent in the human organism. We shall later touch upon the conception of cosmic adjustment. We may say that there is a real sense in which Sirius is in "virtual contact" with the eye and the brain of the spectator, as G. N. Lewis maintains. In Schrödinger's language, the waves which constitute Sirius are immanent in the wave-configuration which constitutes my organism. If the wave-action of Sirius is sensed as light, the energy- configuration of Sirius is immanent in my eye and brain, though its intensity decreases with the square of the distance. Hence the destruction of Sirius would make an immediate difference to my experience of it. If you reply that it has been proved that light moves 186,000 miles a second, I can retort that it has also been proved by the Michelson experiment that light does not move in the ordinary macroscopic sense, for the motion of the earth makes no difference to the motion of light. In the case of light, the moving body is always at the center of the sphere of vibration, while in the case of any other vibrations, such as those of water or sound, the moving body, from which a disturbance is started in the medium, would intersect the sphere of vibrations and produce interference. Light, in other words, behaves, with reference to a body moving in its direction or away from it, as though the body were stationary. The duality of causal communication and cosmic

immanence is only another phase of the duality of particle and wave – a duality which seems to be pervasive in nature. The upshot of this discussion is that science furnishes a justification in terms of cosmic structure for our direct consciousness of reality.

It is plain that the position, suggested in this paper, is one of universal relativity. But relativity needs to be defined. Some have maintained that it always means subjectivity, *i.e.*, relation to an observer. Others have maintained that it must always be conceived as objective, *i.e.*, independent of the observer. Obviously relativity requires analysis. We must distinguish between objective relativity, which is due to the conditions of nature independently of the attention and interest of the observer; and subjective relativity, *i.e.,* relativity of judgment where the history and interest of the observer are involved. As regards objective relativity we must distinguish physical relativity, due to conditions in nature which are independent of the percipient organism, and organic relativity, in which the organism is part of the matrix which must be postulated in nature in order that we may understand the causal conditions of the qualitied situation which we are immediately experiencing. Both physical and organic relativity are objective in nature, *i.e.*, they do not depend upon the percipient's attention and interest.

We have defined objective relativity as relativity in nature which is independent of mind, *i.e.*, of attention and interest; and we have distinguished two types of it, *viz.* physical and organic relativity. We must now illustrate these. Physical relativity has become part of our physical outlook on the world because of the epoch-making work of Einstein. Einstein has advanced two theories of relativity, the special or restricted theory, and the general theory, which is a theory of gravitation. The special theory is a highly artificial conception and has little metaphysical significance. Its contribution, so far as it concerns us, is that all observations of nature are made from a frame of reference which has perspective relations in space and time to other frames of reference in relative motion to our chosen frame. So long as we make our observations and measurements on our own frame of reference, no problem arises. Everything happens as though our own frame were stationary. The problem arises when we attempt to make observations and measurements having regard to a frame of reference in motion relative to ours. It then appears that the lengths are shortened and the durations (the clock-intervals) are correspondingly lengthened. This effect is supposed to be reversible. The reason for this is that, in our present ignorance, we do not know the absolute motion of anything, but by Einstein's (or rather, Lorentz's) formula of transformation, we can translate the appearances in the perspectives of relative motion into terms of one another. The special theory is obviously a pragmatic dodge to cover our ignorance. But its importance for us is that it deals with physical effects, which, though they must be observed in order to constitute data for science, are independent of the percipient organism.

Einstein's general theory is a theory of gravitation, but it has been universalized by Weyl into a general theory of cosmic adjustment. Both Newton's and Einstein's formulae of gravitation exemplify cosmic adjustment, though in Newton's theory the gravitational adjustment is a direct adjustment of masses to one another in space while in Einstein's theory it is indirect. Instead of bodies directly influencing one another's course in space-time, the bodies change the curvature of space and this determines the course of bodies. But for Weyl the conception of cosmic adjustment has wider implications. Lengths and durations are ultimately conceived as determined by cosmic "curvature," and that explains how measuring rods and clocks which are once congruent when together in space-time may become congruent when again brought together in space-time, irrespective of their adventures in the meantime. Weyl's conception of cosmic adjustment explains the constancy of the electric charge everywhere and the constancy of atomic clocks. Still more broadly stated, it explains the uniformity of nature in its physical and chemical transformations. It involves the principle of immanent cosmic control as well as multiple transformations in space-time, and it is the former which accounts for the regularity of nature. What concerns us here is that such cosmic adjustment is independent of the percipient organism. It is of course true that it is through changes in the percipient organism that we must get our information. But the movements of the planets and the stars and the physical and chemical transformations of nature (including many physical and chemical changes in our own organism) take place whether we are sensibly aware of them or not. The physical conditions of nature vary independently of the organic conditions, and *vice versa*.

In what I have called organic relativity, the organism is part of the situation in nature. The sensible aspects of nature, which furnish our data of knowledge, would not exist unless the organism were part of the matrix of nature. This does not mean that the sensible aspects of nature are relative to mind. Mind in its relation to nature functions as attention and interest. The ambiguous phrases, "in the mind" and "contents of the mind," have played havoc with our modern theories of the knowledge of nature. They are responsible for the solipsism which is implicit in our theories of knowledge since Hume. Philosophers have felt obliged first to throw the percipient into solipsism and then to try to get him out. They remind me of the country doctor who first must throw his patient into fits – because he was "death on fits." Whatever may have been the success of the country doctor, the epistemologists have never succeeded in getting the percipient out of solipsism, once they got him in – not even when they have inflated his ego to the dimensions of the absolute. For functional realism, the sense-aspects are "in the mind" or are "contents in the mind" in no other sense than that they are attended to. Attending to the size, shape or color of a thing does not constitute these sense-aspects. If attention created the sense-aspects we could make them

anything that we might wish. While Berkeley thought that the sense-aspects are created in the perceptual situation, he recognized that they are objective to our interest. They are involuntary and are constituted in relation to objective reality, though for him this objective reality is God and not "inert matter." Since science in his day conceived matter to be inert, he took the logical alternative, that of mind, which he conceived to be active. Now that we conceive matter as energy, his disjunction is no longer coercive. We hold that the sense-aspects of nature are independent of the mind's operations of attending, judging, etc. That mind as an organization of energy can also produce changes in the organism – its motor adjustments, its distribution of energy – is another story, but it holds even so that the immediate sense-aspects of nature are objective to attention.

According to the conception of organic relativity, the organism with its structures of sense-organs and nervous system enters as a causal factor into the conditions of nature of which the sense-aspects are conceived as emergent characters. To say that sense-aspects are emergent characters does not mean that they are a mere accretion to nature and that we must divest nature of them to get to what it really is. Since our only first-hand acquaintance with nature is through our sense-aspects, this view would land us in hopeless agnosticism. But this is a false bifurcation of nature and human nature. Nature is what it does, and action implies reaction. There is no substance which has a character by itself. All properties are emergent. Nature reveals itself as sense-aspects in its action upon human nature. It is colored, it is sweet, it is solid, it is extended, it is rhythmic, if it reveals itself as such in the reciprocal action of nature and human nature. It has been said that our sense-perception has to do with the macroscopic world as contrasted with the world of microphysics. It is assumed that there pre-exists a macroscopic world upon which our senses are molded. On the contrary, our macroscopic world emerges in our sense-perception. Locke pointed out that if our senses were microscopic (using the word in its present sense*), i.e.*, if they could sense the minute constituents and motions of things, we should have a very different sort of world and our senses would be useless for practical purposes. It has been said that we sense only surfaces. Such a view substitutes a consequent function for a preexistent reality, to use Dewey's language. The surfaces are the result of the sensing. The world of microphysics does not present us with continuous surfaces. It is mostly empty space with scattered dots of electrons. It has been said that we must postulate the sensing of material things. This statement exemplifies the same fallacy. Things are called material, not for what they are in themselves, which is meaningless, but because of the group of sense-qualities. To postulate sensa or sensibles is only another instance of the same fallacy. Sensa or sensibles are abstractions in discourse of sensory perspectives.

In saying that nature is its sense-qualities I do not mean to imply that it is only sense-qualities. The energies of nature interact with one another in

other contexts beside those of which the organism is part. Perspectives in nature mean not merely the sensible perspectives which emerge from the organism taking account of changes in the environment, or of the changes produced in the organism of part upon part, but also changes in the environment from part taking account of part in space-time relations. Parts of nature reveal to us "aptness" or "powers" to act upon one another and produce characteristic changes of which we must take account. No doubt, we must discover these changes in nature through "their effect upon our sensible simple ideas" as Locke puts it, but the changes take place independently of such effects. We infer these physical and chemical changes and the properties involved in nature to account for the variation in our sense-qualities. The kettle of water on the fire starts boiling, the wood in the grate turns to ashes, the moon changes its relative position, whether we are sensibly aware of these transactions or not. There are other properties in nature besides sense-properties. These are implied in the changes of our sense-aspects, but they are not dependent upon our sense-aspects. They constitute part of the story of nature. They are not more real than the sense-aspects; and, cognitively, we depend upon the latter for our inferences in regard to the former. In short, organic relativity is part of objective nature as much as physical relativity and is independent of mind, *i.e.*, of our attention and interest.

We must now say a word about subjective relativity. Some philosophers regard it a scandal to admit that there is subjective relativity. But surely it plays a very large role in human experience. If objective relativity is independent of the attention and interest of the observer, subjective relativity varies with the history and interest of the observer, and these in turn vary with the history and interest of the society of which he is a part. It is notorious that our judgments and evaluations of nature, including human nature, vary from time to time in the history of the individual and in the history of the race. The physical course of nature has been apparently constant during the comparatively brief epoch of human history. But what a marvelous series of transformations have taken place on our earth as a result of human interpretation and experimentation. In a fundamental sense, we must regard the transformations of mind and in turn its transformations of the environment as part of the cosmic process. By mind I do not mean a substance in itself with properties in itself. Mind is a name for functions, as matter is a name for functions. Locke had at any rate the right intuition. With the limitation of his analysis we are not here concerned. He understood that by matter we mean certain sensible qualities such as "bulk, figure, number, situation, and motion of parts," together with "powers" in the parts to produce changes in other parts (implied properties). If we mean by material substance certain properties, we have equal right to mean by spiritual substance that which has certain properties. "By putting together," says Locke, "the ideas of thinking, perceiving, liberty, and power of moving themselves and other things, we have

as clear a perception and notion of immaterial substances, as we have of material." This only means that when nature functions in ways which we recognize as mental it is mental, as much as when it functions in ways we recognize as material it is material. There is no sense in saying that nature functions as mental by virtue of its material aspects any more than in saying that it functions as material by virtue of its mental aspects. One might as well say that it functions as colored by virtue of its olfactory aspects. Since substances are postulated to account for functions they cannot be independent of them. In fact, substances are indices of functions and possible functions. The point I wish to stress is that mental functioning is a genuine and vastly important aspect of nature and that the realm of mental functioning has its own history and establishes its own relativity, *i.e.*, the relativity of our conceptions of nature to our further judgments and evaluations and the relativity of these to history. This is the realm of subjective relativity. It must be understood, however, that subjective relativity does not need to mean private or solipsistic relativity. It may be social relativity – relativity to the group – though it would be dangerous to assert that the whole of any individual's inner life is public or can be made public.

The recognition of relativity does not mean the denial of structure. Heraclitus has been very much misunderstood. He meant to emphasize order (*Logos*, *Hodos*), rather than change, though he recognized change as a universal fact. In this he does not differ essentially from other Ionian philosophers. It is by his insistence upon order, rhythm and measure in change that he has a unique place. It is because there is order and equivalence in transformation that we can have predictability and science. The qualitied world of our experience is a world of structure. But structure is not revealed to immediate experience. We do not sense structure. For the revealing of structure another organ is required than the senses. In this insight Democritus and Plato agree. Nor do we get structure by immediate intuition. By intuition we can discriminate white from black, but we cannot in that way arrive at the structure of an atom or of a work of art. I have heard that there are philosophers who believe that they have a direct intuition of all "essences." They must have a wonderful faculty of clairvoyance. They should be able to give us the structure of atoms, molecules, organisms, yea, of the universe, and we could dispense with the plodding, tentative methods of science. Of course, if they only mean that white is white, and black is black, and that you can identify the same black or white, that is no great discovery. A child or even an educated chimpanzee, if it can acquire the linguistic labels, could know as much as that. But there must be an esoteric wisdom, known only to the initiated. For the rest of us the grasping of the structure of things requires both creative thought and experimental testing. This is true equally of the subjective and the objective realm. Most of us do not know the structure of our own mind any more than that of matter by immediate inspection. Whitehead tells

us that feeling is a subjective form. But this is a misunderstanding of Plato's *eros*. Love is not form, but spiritual love is a striving for form. It is true that it is the feeling for form which is the drive in both science and art. We must have a feeling for consistency, unity, harmony and simplicity to be moved to seek to produce form, whether it be to create a scientific theory or a work of art. But immediate feeling itself is as amorphous as is sense-perception. Both indeed imply form in the world of which they are aspects – but only to a creative mind.

While the recognition of form must come through the creative insight of the minded organism, that does not mean that the form is only in the mind. Kant was right that unless the mind possesses structure we cannot discover structure. But ordinarily it is not with the structure of mind that we are concerned. We seek the form in the objective situations in nature. The mind does not dictate the form to nature. It does project form into nature and in this sense we may speak of "the ingression of eternal objects," but this "ingression" is tentative and subject to observation and experiment. Scientific "ingression" is a trial-and-error process – unlike Whitehead's "ingression" from a scholastic God. We seek the structure of things which will account for their responsiveness and we check our conception of it by their responses. It is so that we must discover the structure of mind as well as that of matter. We have an *a priori* faith that there is structure in our qualitied world, but what kind it is can be found out only by trial-and-error experimentation, intellectual and physical. If we came to know the structure of physical things by their responses, so we must ascertain the structure of organisms through their functions. The structure which we conceive to account for reflexes and their conditioning cannot account for the survey, analysis and construction which are characteristic of responses of thinking. No blocking of habits will give rise to thought unless we have an organism with the requisite structure.

The cognitive perspective relation is a real and momentous relation in nature. It has transformed the significance and control of nature in the history of humanity. It is not true, however, as epistemological idealism has maintained, that the cognitive relation is the *ratio essendi*, the ground of existence, of everything. There is an indefinite number of perspectives in nature beside the cognitive perspective. To say that reality cannot be known unless it exists for knowledge is of course mere tautology. The fact that other perspectives of nature may at times enter into the perspective relation of judgment and discourse is possible only because they have existence in their own milieu in nature. Physical and organic perspectives exist whether they are known or not. We must discover them and as yet our knowledge is very limited. But we must not, because cognitive perspectives are not constitutive of other perspectives of nature, ignore the fact that they exist as aspects of nature and involve their own conditions of organization and their own history. Cognitive perspectives or points of view, moreover, are not just

abstractions in discourse. They are energy-perspectives and powerful to transform nature. They involve the whole organism at a certain level of organization and functioning. And they do not exist *in vacuo* but function in the milieu of nature, of which the social milieu is an essential part. The cognitive relation has its own characteristic duality[7] of subject and object or referent and relatum. It is in the cognitive relation that our qualitative perspectives become data. They are not data in themselves, but only for cognitive experimentation. It should be pointed out that cognitive duality of subject and object does not coincide with the distinction of subjective and objective perspectives, previously made. Object in the cognitive relation may be physical, organic or mental. It means any aspect selected as a datum by the cognitive interest. It may be gravitation or a toothache or $\sqrt{-2}$. Cognitive perspectives, therefore, may cut across any other perspectives, or rather, any perspective may become a datum for the cognitive interest, including the cognitive interest itself. But this has nothing to do with the existence of other perspectives in their own milieu of nature. Since all perspectives are selective relations in nature, the cognitive perspective enjoys no metaphysical priority over others. It is only one type of selective relations in nature. It involves indeed a specific type of organization of the referent and a specific type of community with nature. But that is true of other perspectives as well. The cognitive relation is distinguished from all other types of adjustment in that in it error exists as part of the adjustment. There is no error in physical or organic perspectives. Error is due to the striving at creative anticipation of nature by means of ideas. This is the realm of adventure of creative mind.

It has been said that thought is talk, and it is true that social communication is a necessary medium for the development of thought. But we cannot say that talk is thought. We know of too much talk that does not reveal thought. Language and communication are not sufficient to account for thinking. There must evolve in nature a structure with its own peculiar restlessness. Thought is evolved as an expression of the urge for life and a more abundant life. It is an aspect of vital adjustment and itself is a vital function as much as digestion. For thought to come to actuality there must evolve not only certain cerebral structures and certain vocal structures, but also a social milieu for expression. Thought presupposes the urge of our whole biological history, of our social milieu, as this becomes a part of us, and the immanent cosmic *eros* or love for form. It analyses our qualitative experience. It particularizes or universalizes its selected qualitative aspects according to its interests. Particularity is no more given than universality. Both are predicates in significant discourse. By means of language, thought fixates qualitative experience into "essences" or universal predicates, and it creates ideal structures by means of which it tries to unlock the inner nature of things. But it has no key

[7] See the author's *Truth and Reality* (1911), pp. 138–141.

to structure except function and its conceived structure must prove relevant to function as revealed in our experience of nature. As part of vital activity, thought first of all works for the furtherance of biological wants, but it may emancipate itself from these. It may become absorbed in the interest in comprehending the structure of things and become pure science, or it may set itself to incarnate form in objects which shall satisfy its feeling for beauty, without reference to utilitarian demands, and express itself as art. But as an activity it must be grasped in its kind and cannot be reduced to the simpler activities of reflex and habit. As a vital activity, thought involves the whole organism with the whole gamut of structures and activities – sensory, motor, affective, mnemic, ratiocinative – in a milieu of nature which includes society.

Thought is deeper than rationalization. It is an urge born out of the unconscious depths of our racial and personal life in the cosmos, seeking light and meaning in an apparently confused world. At the lowest level of nature things exist in a vague, undifferentiated mutuality. But in the course of time, through an immanent urge in nature, structures and organs become differentiated, so as to respond more adequately to the environment and make a fuller life in nature possible. So senses are constructed. Then other structures are evolved to respond in time as well as in space, such as habit and memory. At length there is the consciousness of the small voice of spirit, midst the babel of impulse. There is the reaching out for form, the fashioning of intelligence, the feeling for beauty. Who can doubt that spirit is as truly part of nature's striving as are the structures and organs which have to do with our primitive biological needs? And does not spirit require its own characteristic environment and its own characteristic satisfaction? At any rate there are those who do not live by bread alone and who regard the primitive biological needs as mere means to the attainment of the values of spirit – the values of truth and beauty. If we call such satisfactions a "balanced metabolism," they at any rate involve a level of organization and satisfaction different from that of a sound digestion, though this is not to be despised. They mean the establishing of a type of *rapport* with the environment other than mere physical and biological adjustment. As qualitative satisfactions they are a whole-response to nature of another order – the response to spirit in nature.

Since the ideal aspects of our experience of nature are as real, as much part of nature, as the sensory, the ideal aspects imply mutuality with nature that is appropriate to their character. If we are interested in what sort of universe makes our sense-aspects possible, we should be interested in what sort of universe makes our spiritual experience possible. It is true that in either case human nature is part of the situation and gives its own character to the result. Our experiencing of nature and our interpretation of nature are human, all too human. We cannot speak for God, as Kant truly saw. But we must not forget that human nature is part of the cosmic matrix and must be understood in that matrix. This is as true of the spiritual level of thought and

appreciation as of the level of sense. In either case, it is the cosmic matrix which furnishes the stimulus to adjustment and at length rewards life with such rapport as its capacity for responsiveness makes possible. Beauty is not all in the percipient, though the percipient must be properly organized. While the appreciation of beauty is an organic adjustment, it is not all organic, but an adjustment of the organic to the harmony in nature.

Section Four

Evaluations of Boodin on Pragmatism

REVIEW OF TRUTH AND REALITY

Charles B. Vibbert. "Review of John Elof Boodin, *Truth and Reality: An Introduction to the Theory of Knowledge*." *Journal of Philosophy, Psychology and Scientific Methods* 12.2 (21 January 1915): 48–53.

The aim of the volume before us, as the sub-title implies, is primarily epistemological. The author promises in the preface to follow it up shortly by another volume on metaphysics, to be entitled "A Realistic Universe," where some problems suggested in this book will be dealt with more fully.

The author's position is already known to the philosophical public, since eleven of the seventeen chapters which make up the volume have already appeared in substantially their present form in various American philosophical journals. Professor Boodin makes open profession of pragmatism, but pragmatism of a very special brand, the pragmatism of William James to whom the volume is fervently dedicated. In fact, one of the chief merits of the presentation is the attempt made to rescue pragmatism as a method and as a theory of truth from the unwarranted developments of the instrumentalists and the humanists. It is safe to say that no other disciple of James has presented his position so fully and so accurately.

The work is divided into four parts, in which are taken up at about equal length the four problems: I. "Truth and Mental Constitution"; II. "The Nature of Truth"; III. "The Criterion of Truth"; IV. "Truth and its Object." Under these captions all the main problems bearing on the nature, function, and verification of reflective thought, to which the pragmatic controversy has called attention, are not only touched upon, but, for the most part, treated in full.

The plea for philosophical tolerance with which Part I. opens, based as it is on our differences of temperament and the different demands which the various aspects of our nature make on the world, is strongly suggestive of the like indirect plea for pluralism in philosophical doctrines at the opening of James's "Pragmatism." "Why should not every sincere man express his life in a philosophy that seems reasonable to him at the time of its experience now? Thus not only man, but the different moments of man, become the measure of all things.... Agreement and sameness are practical necessities for the sake of common action, but outside the elementary qualifications for social life they are the bane of progress."

The author's fundamental assumption with regard to the nature of mind, an assumption which dominates the entire volume, is implied in the very title

of the second chapter, "Mind as Instinct." This assumption, not phrased in exactly these words by the author, may be elaborated thus: Mind is primarily an active process; consequently its various stages or levels of development, its structure and its forms, must be accounted for in terms of this activity. In explanation of the genetic development of the three main stages of mind this assumption takes on a more specific form: "All our fundamental adjustments or categories, viewed from the point of view of individual development, are instinctive or organic adjustments; the stimuli, which constitute the environment, are simply the occasion for calling into play the structural tendencies of the organic growth series." Corresponding to these stages of development we may expect to find sets of forms or categories which serve as the structural framework of each, and under which, accordingly, knowledge at its various levels is organized. The table of categories, though suggested by Kant, must be corrected by and brought into accord with the splendid work done by recent genetic psychology. The levels of intelligence and the corresponding categories are: (1) The Perceptual Level, with its categories of space, time, and habit; (2) The Level of Reproductive Imagination, involving continuity, similarity, and set; (3) The Level of Empirical Generalization, implying the four syntheses of quantity, quality, cause and effect, and individual interpretation or substance. Just what the relation is between these sets of categories and the genetic stages set forth in the preceding chapter is not made clear. Furthermore, though the author insists, in accord with his fundamental assumption, that intelligence is primarily conative, that intelligence remains an instrument, however elaborate, for fulfilling the demands of the will, the relation of these categories to the volitional activity is not sufficiently elucidated. Are they, like the postulates of truth considered later, posited by some will-to-be-intelligible somewhat after the manner in which Professor Rickert conceives them? Or are they stereotyped modes of reacting upon the given material of experience? Or are they, as Kant conceives them, the conditions which alone make possible our experience such as it is? The author could, no doubt, clear up these points by further elaboration. As the presentation stands, it is defective.

In part II., under the caption "The Truth Process," the author differentiates reflective thought from types of meaning of a simpler sort such as perception and associative memory, and from other forms of ideal synthesis, like thought, which involve ideal construction and organization by purpose, such as esthetic wholes; then, after pointing out the limitations of language as an adequate expression of thought, he criticizes some of the recent psychological work on thinking on the ground that the thinking investigated is not real thinking, but only association of ideas. Likewise the discussion with regard to the possibility of imageless thought is bootless since it is not the type of imagery which characterizes thought, but selective leading. The thought attitude implies the active leading or control of processes by a conscious, organized conative

purpose. The conative leading constitutes the core of thought, not the imagery. Just as bootless is it to characterize thought by the feeling of effort which accompanies it, but may or may not come to consciousness. The truth process may now be defined more precisely, first with reference to its structure or morphology, secondly with reference to its content. The judgment, the forms of which constitute the morphology of thought, is presented as a fundamental unity of thought moments which starts with negation or the need of fresh adjustment, whether as the result of practical necessities or baffled curiosity; it proceeds through the trial stage of ideal construction and verification (hypothetical judgment), developing in advanced knowledge into the disjunctive schematization of alternates (disjunctive judgment): and its perching-place, after the long or short flight, is the adopting of a provisional scheme for conduct (categorical judgment). The concept thus becomes not the beginning of the thought process, but its terminus. It is the completed form of the categorical judgment at any stage of the history of thought – a conscious definition, a definite programme of action. Turning now to the problem of the content of truth, Professor Boodin accepts Locke's doctrine that the process of truth has to do primarily with the activity of relating. From the standpoint of *psychological* analysis, the attempt to analyze relational consciousness into kinesthetic images and sensations confuses the physiological concomitants and their sensations with the nature of the thought process itself. From the standpoint of *epistemological* analysis, we are confronted with the question whether these relations are to be taken as internal relations or as external relations, a question which plunges us into the controversy which has raged between the neo-realists and the absolute idealists. In solving this problem our author appeals to a principle, christened pragmatic, of which he makes large use in resolving other doctrines which appear to be mutually exclusive – the principle that we must acknowledge the universe to be what we must *take it as*. If now we accept this principle arid appeal strictly to our finite experience only, we must take the universe as in part implying internal relations or relations of teleological significance; in part as capable of being taken in terms of external relations, or at least external to our finite and fragmentary purposes. The pragmatic movement has emphasized the function of truth in relation to life as a whole, the regulative function of thought in experience. But is this the whole story? Does not the truth process always presuppose also certain laws or postulates which, whatever their origin or significance in the structure of the real, must still be acknowledged if thought is to pursue truth? There are four such postulates: the law of consistency, the law of totality, the subject-object law, and the law of finitude. The epistemological necessity of these laws can only be proved by showing that, in the actual social procedure of thought, no instance which does not imply them can be cited without making truth impossible, which would show that they must hold for all cases of truth. They have ontological

necessity only in so far as we admit truth as an ontological fact in the universe. Thought, then, we must conclude, is an activity of the will, predetermined as regards its form by certain presuppositions which are posited by the will to think. It is not the only activity of the will. The will may be instinctive in its activity, it may be perceptual, it may be guided by concrete images, it may dream. But when the will sets itself the task of thinking, whether for purposes of practical necessity or for the enjoyment afforded by the game of thinking itself, the will accepts or postulates certain norms, a constitution of thought.

In Part III., by way of introduction to the central problem of pragmatism, the criterion of truth, the author orients us into the movement by sketching its history "From Protagoras to William James." Things exist and are what they are because of the differences they make to human nature – this is the essence of pragmatism. In other words, we can only speak of those things as existent that make a difference to human nature, either directly as immediate experience (the contention of Protagoras), or indirectly as assumptions needed to account for such immediate experience as our perception with its microscopes and telescopes furnishes us (the contention of Plato). Pragmatism may be further defined as scientific method conscious of its own procedure; and if it be maintained that, in this case, it has nothing new to offer, it my be replied that there is always need of a renaissance of the pragmatic consciousness in science. If, now, we attempt to define pragmatism in terms of what it is not, we can show that it does not imply that the true and the useful always coincide; it is not equivalent to humanism, the doctrine that since reality must pass through human nature in order to be known, therefore the nature of reality is made over in knowing it: it is not committed to the instrumental point of view as regards concepts, for truth must always be imitative of its object to a certain extent; it does not necessarily fall on the side of realism except in so far as it intends a world beyond our finite cognitive purposes. Can there be any final distinction between meaning and validity? If we use meaning in the sense of pragmatic meaning – the difference which a situation makes to our further procedure, whether practical or formal – then there can be no final dualism between the meaning of a proposition and its truth. The meaning which molds itself on the constitution of reality, which leads to the intended consequences, is precisely the *valid* meaning. Though both realists and idealists have joined in maintaining that truth is agreement with reality, they alike fail to break up reality and so fail to show the different meanings of agreement, according as truth is a copying process or an artificial device. Agreement *means* agreement only when we intentionally select with reference to the realization of some purpose. Agreement has a twofold significance: (*a*) the instrumental relation of the knowing attitude to its object and (*b*) that of sharing, to use a Platonic term. (*a*) In so far as reflective thought sets its own conditions, irrespective of the inner meaning of the processes to which it refers, aiming at prediction or

control of the object as a means to its own purpose – in so far thought is instrumental. (*b*) But some objects of knowledge must be recognized as having a meaning of their own, a rational purpose and value which we must acknowledge. The fulfilment of our purpose here is conditioned upon partaking of an extra-individual realm of meanings, respecting them and sympathizing with them. Though it is universally recognized now that we must arrive at truth through our human purposes, though human nature with its purposive selection determines the *meaning* of the object, does it, as cognitive, determine the *existence* of the object? No: human nature contributes to nature the significant system of cognitive relations; it does not contribute existence.

In defining the relation between truth and its object in Part IV., the author develops his own standpoint of pragmatic realism. Realism is an epistemological attitude and has to do with the relation of the cognitive meaning to its object. Realism does not deny that objects to be known must make a difference to reflective experience. What realism insists is that objects can also exist and must exist in a context of their own, whether past or present, independent of the cognitive subject; that they can make a difference within non-cognitive contexts, independent of the cognitive experience of which the latter *a posteriori* must take account. In reply to the objection that to think an object is to think it as experienced, therefore it must be experienced – an objection based on the assumption that only like can make a difference to like – the realist insists that there can be different universes of experience which can make a difference to each other; and also that what is non-reflective or non-meaning can make a difference to our reflective purposes, or *vice versa*. Objects, then, enter into different contexts of which we may distinguish three types: the physical context, the social context, *my* context; and each of these contexts can make a difference to one another. In the two final chapters Professor Boodin paves the way for his promised volume on "A Realistic Universe" by making a plea for metaphysics and defining its three main problems, the problems of knowledge, of existence, and of value; and by pointing out the reality of religious ideals. These chapters are suggestive as indicating the direction in which this type of epistemology leads; they are not essential to the main argument of the book.

Professor Boodin agrees with the rank and file of pragmatists in insisting on the conative, purposive nature of mind, in conceiving of truth as an affair of leading, in making the test of the real that which can make a difference to something else, in maintaining that reality is what we must take it as, in appealing to the immediate. It is primarily in his anti-humanistic and anti-instrumental doctrines that we come upon new points of view: in the distinction drawn between the two types of agreement, instrumental and sharing; in making significance a much narrower term than existence; in the emphasis on the various types of contexts into which the same object may

enter. All these doctrines, be it noted, make for realism and away from idealism. The realistic motive dominates the volume.

The appeal to the immediate, usually under some such form as this: "The real is what we must take it as" (Cf. pp. 295, 301) is constantly made. But just what is meant by the immediate is left as vague in this argument as in all other pragmatic writings. In the early part of the book the immediate seems to be identical with the perceptual, as James tends to maintain; later on conceptual construction is included under the immediate; still further on in the argument the immediate is made to include that type of agreement known as sharing. Such ambiguity may make for a pluralistic outlook upon the world; it certainly does not contribute to clear thinking. It is to be hoped that the author will clear away in his later work the fog which as yet envelops the immediate.

REVIEW OF A REALISTIC UNIVERSE

F. C. S. Schiller. "Review of John Elof Boodin, *A Realistic Universe*." *Mind* 28.3 (July 1919): 362–365.

Prof. Boodin's Preface tells us that "this volume on metaphysics is the sequel of a volume on the theory of knowledge, entitled *Truth and Reality*, which was published in 1911. The two volumes furnish a survey of the field of general philosophy from the point of view of pragmatic realism." Its attitude is "an attempt to apply scientific method to philosophic problems," and "the pragmatic method as applied to metaphysics means that we must judge the nature of reality ... by the consequences to the realization of human purposes, instead of by *a priori* assumptions." From his introductory chapter we learn further that metaphysics, since to philosophize we must think, implies that there are valid rules of thought, and "a faith in their fitness or relevancy to our world" (p. xv). Unlike Mr. H. G. Wells, he entertains no 'skepticism of the instrument', but thinks "we must trust the instrument at the outset," which is "fundamentally an attitude of the will." So "somehow the laws of thought must be the laws of things," but they "must be tested by their success in actual use" (p. xvi). So our "faith in the relevancy of thought," must be confirmed. Similarly, though philosophy "exists in part for ennobling life," and "must satisfy our emotional and volitional nature, as well as our intellectual," it is yet "science not art," nay "the oldest of the sciences – the mother of science." Actually, however, Prof. Boodin's method is to attempt to solve the problems of metaphysics by selecting five scientific conceptions now current, and following them whithersoever they lead. These he believes to be irreducible into terms of each other (p. 385), and regards as "the summa genera in the reflective evaluation of the character of the world" (p. 391).

His list is composed of (1) *Being*, "the stuff-character of reality"; (2) *Time*, "the flux-aspect" of reality; (3) *Space*, which is "more than a conceptual limit," since "interstellar space seems to be practically pure"; (4) *Consciousness*, since "it is absurd to suppose that our conative attitudes and organized meanings become atoms and molecules when we are not aware of them," and which is conceived as "a neutral light," that "does not create distance nor does it create meaning" (p. 399), and is "always an aspect of the situation which we call *interest*" (p. 400); (5) *Form* or direction, which raises the question of validity, and "must somehow condition the survival of structures" (p. 403)

Now it is evident that a method like Prof. Boodin's has very considerable attractiveness. To make the achievements of modern science relevant to the secular perplexities of philosophy gives to metaphysics an air of solidity in which its fine-spun speculations have usually been lacking, even though Prof. Boodin's five categories may look to some like five bluebottle flies caught in a web of gossamer, and suggest a doubt whether it can sustain such weighty bodies. However, Prof. Boodin writes with a refreshing sense of realities, and with a praiseworthy clearness and directness of style, and is withal so good tempered and tolerant about his metaphysical selection (as a genuine pragmatist should be!) that he very effectively disarms his critics. Hence the remarks that follow should be taken less as objections than as inquiries and cues for reflexion.

So long as a philosopher shrinks from undertaking the (probably futile) task of 'deducing' his categories and supplying a rigid proof (almost certainly impossible) of their ultimateness, he cannot in reason require every one to approve of his selections, and has in principle to admit that as systematic, impressive and satisfactory structures can be erected out of different materials as out of a different arrangement of the same materials. Tastes differ in metaphysics as in love, and Prof. Boodin's 'Big Five' do not appeal to every one. Thus 'Being' has seemed pretty null and void to others besides Hegel. Moreover, 'Value' penetrates it, transforms it, and perhaps finally absorbs it. 'Change' is the presupposition both of 'Space' and of 'Time' and pervades them both; it seems clear that the experience thereof is far more ultimate than the abstractions out of which we build up our scientific conceptions of Space, and Time. 'Consciousness' is either mere philosophic jargon, or the thinnest possible abstraction from concrete personality, while the latter may be found in ultimate analysis to be as all-pervasive as 'Value'. 'Form' is a category which it was natural for the artistic craftsmanship of Greece to hit upon, but it has never shown itself susceptible of scientific definition. So it was never fully analyzed and remained full of picturesque obscurities. Since then it has developed an abundance of tantalizing ambiguities and become as elusive as 'validity' or 'law'. To justify its prerogative use, it hardly suffices to declare that "Plato and Aristotle have shown that in higher ideal realization it is not necessary that the form itself should move in order to produce movement, that is, that the form should possess energy. The beloved may be indifferent to the lover. Beauty moves us by its perfection" (p. 378). Only, surely, if it does not disdain to reveal itself to us. And if it reveals itself in any way, if only by agitating ether waves, it *is* moving and acting on us in the scientific sense. So that the 'unmoved mover' no longer has any scientific meaning.

But an even more fundamental question may be raised about Prof. Boodin's method. Our existing stock of ideas, including not only those with a recognized scientific status, but also those employed by common-sense, and the ideals, idols, and speculations of philosophy, has been accumulated by our

past dealings with reality, and has resulted from our protracted efforts to come to terms with it. The most, therefore, that can be claimed for our idea is that they should be adequate, *collectively*, to the manipulation of the world for human purposes. But it does not follow from this contention either that any particular selection from them should be adequate, or that, having been evolved for different and only distantly related purposes, they should all be concordant and consistent with each other. Accordingly, we find that different methods suit different subjects (*e.g.* mechanism and teleology), that conceptions used in different subjects are incompatible with each other, and that conceptions may continue in use which are inherently self-contradictory, *e.g.* that of an omnipotent and yet benevolent deity. For if a conception is a psychological conflation of emotional demands and vital attitudes, this is quite natural; its 'self-contradiction' will then merely embody the conflict in the soul that generated it. Such discrepancies, however, are not a serious scientific inconvenience; for the sciences do not claim finality for their conceptions, and can continue to cherish the hope that they will hereafter grow harmonious, while in the meantime the use of one conception for one purpose does not exclude the use of another for another. Metaphysical systems, however, in so far as they aim at consistency, must make selections, and selections imply alternatives and alternatives a reference to desirability and comparison of values. Does it not follow that no metaphysic that has relation to any empirical material can lay claim to cogency or finality?

It has, however, like every scientific conception, a duty laid upon it which it cannot disclaim. It is bound to make quite clear and unmistakable the meaning it attaches to the terms it operates with. And it will usually be found that metaphysicians leave some of their essential terms in impenetrable obscurity. In Prof. Boodin's case this obscurity would appear to surround especially his notion of 'validity'. In particular its relation to 'value' is not explained, though page 188 makes a convenient distinction between 'value' (subjective), and 'worth' (objective). According to page 137, value is 'made possible' by 'consciousness', which here does not seem quite so 'neutral', as it is officially supposed to be. But how is 'value' related to 'validity'? 'Validity' would seem to be objective; yet on page 340 it has degrees, like 'value'. And on pages 339–41 we are treated to the old Platonic contention against Protagoras, dog-faced baboon and all. There must be an absolute standard, absolutely 'valid'; for otherwise the possibility of 'validity' is denied, "all argument must stop," and "one opinion is no truer than another." If no notice is taken of the Protagorean reply which, as I have shown in my *Plato* or *Protagoras*? is given and *not* refuted in the *Theaetetus*, the logical conclusion is that "radical empiricism is impossible as our ultimate philosophy," because with it "no ideal could be valid." Thus 'validity' becomes vital to Prof. Boodin's scheme, and the *deus ex machina* which assures it is 'form'; but I can find no reason why 'forms' should pre-exist, and not be formed, and

transformed, in the process of the real, or why 'validity' should not arise in the course of experience out of agreements about values.

A similar obscurity besets Prof. Boodin's "valid rules of thought," and the dictum that "metaphysics implies logic" (p. xv). Aye, but what sort of logic? The traditional Formalism, which sacrifices all meaning to'validity' it utterly fails to realize? Or a more reasonable sort, which prefers the real values of 'material' truth to unsatisfied craving for 'formal validity', and is content to conceive its 'laws' as the postulates of intersubjective intercourse which can be *hypothetically* applied to the world of things and used successfully to calculate the behavior of *some* of them for some purposes? I cannot but feel that there are dark corners in Prof. Boodin's 'realistic universe' which have never been illumined by the sunlight of a thoroughgoing pragmatism.

INTRODUCTION

Varieties of Pragmatic Naturalism

George Santayana (1863–1952) and Clarence Irving Lewis (1883–1964) were educated at Harvard University, studied primarily under William James and Josiah Royce, and became professors of philosophy at Harvard. The philosophies of Santayana and Lewis were in large part reactions to, and developments of, the views of empiricist James and idealist Royce as they contended for philosophy's soul during their years as colleagues from 1882 to 1907. Caught in the crossfire of these two giants, many Harvard graduates from that "Golden Age" of Harvard, including John Elof Boodin, Ralph Barton Perry, Wilmon Henry Sheldon, Horace Meyer Kallen, William Pepperell Montague, Jr., and Arthur Oncken Lovejoy, were similarly inspired to search for creative philosophies of adjudication and compromise.

Santayana himself added to this extraordinary atmosphere while teaching at Harvard from 1889 to 1912. Lewis took a course on Plato with Santayana, but Santayana's own philosophy apparently had little influence on Lewis's early commitment to idealism. Two years after receiving his Ph.D. in 1910, Lewis published a sharp rejection of naturalism, taking Santayana as his primary target and using Roycean principles as grounds for criticism ("Professor Santayana and Idealism," in this volume). However, Lewis did not accept absolute idealism's vision of a supreme mind whose perfect knowledge continually sustains all reality. By instead adopting a fallibilistic epistemology of empirical knowledge, Lewis gradually approached the pragmatist position of James and Charles Sanders Peirce by 1920. During those years Santayana had accepted some aspects of pragmatism as well, attached to an uncompromising critical realism.

Santayana and Lewis arrived at distinct pragmatic naturalisms by the 1930s, offering alternatives to rival systems destined to compete for dominance in Anglo-American philosophy during the remainder of the twentieth century. The primary alternatives included John Dewey's pragmatic naturalism, Alfred North Whitehead's process philosophy, the logical empiricism of the Vienna Circle, and Harvard philosopher W. V. Quine's reductive materialism. Santayana founded no school, but his non-reductive materialism lived on in the form of epiphenomenalism which has to the present day stubbornly resisted reductive materialism. Lewis's variety of pragmatism influenced Quine, who took the Edgar Pierce Professorship at Harvard after Lewis retired, and it also influenced others who looked to

empirical science as the sole source of knowledge. Intriguingly, Quine's ontology of materialism echoed Santayana's own convictions, even as Quine sought to eliminate the realms of spirit and essence that Santayana defended. Also significant is the way that Quine strengthened Lewis's fallibilistic empiricism by repudiating the analytic/synthetic distinction vital for Lewis's own epistemology.

The chasm between Lewis and Santayana on the one hand and Quine on the other opened even further concerning the status of "meanings" and "the given" in experience. It became fashionable in mid-century Anglo-American philosophy to deny the analytic/synthetic distinction and challenge logical positivism's reliance on knowable phenomenal experience. As a consequence, it became convenient to cast scorn upon the notion of "the given." When philosophers then spoke of the given, they were usually referring to an allegedly infallible type of perceptual knowledge. Quine's "Two Dogmas of Empiricism" questioned whether the foundationalist reduction of discourse to sense-datum language is possible, and declared that the very notion of the given was bound up with the spurious analytic/synthetic distinction. When Quine concluded by recommending that philosophy abandon the idea that there is a "linguistic component and a factual component in the truth of any individual statement" he was understood to be attacking not only logical positivism but also his colleague Lewis. Wilfrid Sellars, who had taken a course titled "Theory of Knowledge" with Lewis in the late 1930s, later announced his own renunciation of "the myth of the given." In "Empiricism and the Philosophy of Mind" (1956), Sellars was similarly understood as directly challenging Lewis. Sellars actually ended up fairly close to the classical pragmatists in his later years, and arrived even closer to Santayana by synoptically coordinating perception, intentionality, and rationality with scientific realism. Quine, however, was intent upon behavioristically and physicalistically eliminating concepts, meanings, and experience from reality. Only the lingering pragmatism of his fallibilistic yet realistic philosophy of science still linked Quine with his Harvard predecessors.

Did Quine and Sellars really have a target in Lewis? Lewis did hold the Kantian view that the mind approaches new experiences with a framework of meanings, and openly allied his epistemology with much of Rudolf Carnap's logical positivism in the 1930s. With Santayana, Lewis believed that there is a portion of experience for which the mind is not responsible. However, neither philosopher believed that this portion presented itself as indubitable knowledge. Both Santayana and Lewis, like fellow pragmatists Peirce, James, and Dewey, accepted the realm of empirical experience as having legitimate reality, even as reason carried belief beyond present experience. Scornful of solipsism and positivism, each of these pragmatist philosophers philosophized about the nature of the integration of human experience with wider realities. They all agreed that this integration did not

require the supreme mind of absolute idealism, and they were similarly agreed that crude materialism was inadequate. In Santayana's terms, while the realm of matter is the sole power and agency, the intuition of meaningful essences that occurs in the realm of spirit is no less real. In Lewis's terms, the organization of experience is only partially under the control of the mind's concepts. Both Santayana and Lewis find that when the mind experiences such partial of control of experiences, the mind automatically believes that these given are experiences of mind-independent existences. They also hold that the remaining task of knowledge is to discover where these existences can be coherently related with the rest of experience. Even a hallucination can be a real hallucination and explained by relating it with certain other realities. However, for Santayana and Lewis (again agreeing with earlier pragmatists), no "given" is automatically granted epistemic status as "known" and certainly not granted infallible certainty independent of the context of inquiry.

The disagreements between Santayana, Lewis, and Quine can be helpful surveyed without too much distortion by noticing that they all start from some pragmatic approach to knowledge, then endorse some type of naturalism which each believes best harmonizes with their type of pragmatism. Santayana pragmatically endorses materialism as common-sensically accepted by ordinary practical living, and then infers from materialism that knowledge occurs in the separate realm of spirit where consciousness tracks but does not influence the processes of nature. Lewis's pragmatic epistemology endorses a scientific realism of natural things that are continuous with human experience, but requires that this scientific realism cannot replace the very lived experience that science is supposed to assist. Quine holds that to know reality is to pragmatically accept one or another scientific theory about reality, and supposes that science's realities must therefore be exclusively real. Each philosopher's naturalism determines the final shape of their epistemology: Santayana's materialism ensures that knowledge impotently watches the signs of unfolding reality; Lewis's scientific realism is forbidden from calling into question the consciousness that grounds scientific inquiry; while Quine's scientism demands that cognitive and behavioral psychology eliminate consciousness and take over from epistemology the task of discovering how nervous systems transform sensory stimulations into intelligent representations of reality.

This introduction to Santayana and Lewis proceeds to discuss some selected details of their pragmatic naturalisms, as illustrated by the selections of writings presented in this volume. Of necessity, only those aspects of their philosophies that directly involve pragmatism are mentioned here. For fuller expositions of their philosophies, readers may consult the concluding bibliography. Of particular value for understanding their naturalistic pragmatisms, five books have special place. On Santayana: Henry Samuel Levinson's *Santayana, Pragmatism, and the Spiritual Life*, Timothy L. S. Sprigge's *Santayana*, and the Library of Living Philosophers volume on *The Philosophy*

of George Santayana, edited by Paul A. Schilpp. On Lewis: the Library of Living Philosophers volume on *The Philosophy of C. I. Lewis*, edited by Paul A. Schilpp, and also Murray G. Murphey's *C. I. Lewis: The Last Great Pragmatist*. For convenience, most references to Santayana's writings are to the one-volume edition of *Realms of Being*.

George Santayana: The Faith of a Materialist

Santayana preferred to use time-honored labels for key philosophical concepts and theories. The four realms of being in his materialism are the categories of matter, spirit, essence, and truth. For Santayana, matter denotes that realm of self-sufficient and efficacious power, having some key general features: matter exists in physical space and physical time, it is unevenly distributed, and it is continually changing in discrete events (*Realms of Being*, pp. 202–203). Precisely because matter is essentially active and particularized, material objects take on a procession of properties and forms, or "essences," through the flux. If matter were static and homogeneous, no specific properties could ever apply to any parts of it; since matter does in fact exemplify various specific essences over time, matter truly has these properties and so the realms of essence and truth should be distinguished from the realm of matter. A hypothetical omniscient knower would be acquainted with all exemplified essences and hence the entire realm of truth about matter's activities; for several reasons described below, any human knowledge will fall short of such absolute knowledge. Neither the realm of essence nor the realm of truth exist in their own right; essences and truths are always of some realm (material or spiritual) which does exist.

Portions of matter achieve life which struggle for brief existence within environments. Sufficiently sophisticated organisms generate conscious feeling and awareness, and thus the realm of spirit comes into existence. Santayana reserved the term "psyche" for those habits of material organisms that permit their characteristic energetic behaviors (Sprigge, pp. 95–99). Offering no explanation for why living matter should generate spirit, Santayana was content to accept this evident fact, and notes that any change *per se* is equally mysterious. The distinction between spirit and psyche is crucial for following Santayana's philosophy any further. The human psyche is responsible for our capacities of rationality, reflection, intelligence, deliberation, and the like. There are, strictly speaking, no laws of spirit, although there are scientifically discoverable laws of psyche. Unlike psyche, the realm of spirit has no causal powers or relations (*Realms of Being*, p. 332). Matter and spirit, while both exist, have no causal relations with each other. Santayana felt that he had James's weighty psychological authority backing this position, as James had argued in the 1880s that feelings like emotions are consequent upon physiological events and do not cause them.

Santayana may have been aligned most closely with other pragmatists in his first systematic work, *The Life of Reason* (1905–6). Like any pragmatist, Santayana admitted the practical effects of reasoning and frequently used the term "knowledge" to refer to practical intelligence's facility with predicting and controlling the environment. Spirit has quite another destiny as the sensuously and imaginatively appreciated spectacle of consciousness. Santayana sometimes proposed that the gradual transition from vegetative to animal life would naturally generate spirit as psyche's attention to external objects grows in importance. However, Santayana expressly rejected James's hypothesis that consciousness was a contingent development that has shown to have survival value by somehow being efficacious. Santayana chose the alternative hypothesis that the animal psyche necessarily generates spirit. Santayana's position is not identical with Descartes' dualism since the realm of spirit has no independent ontological existence but always depends on matter. Spinoza's monism may also be viewed as a forerunner to Santayana, although Santayana did not propose that spirit really is matter in some mode or manner. The label of epiphenomenalism is best for his philosophy, since for Santayana, impotent spirit cannot be ontologically or descriptively identified with any part, phase, or aspect of the material realm, but is destined to only be an accompaniment to matter's flux. Although Santayana did not hold that the past strictly determines the future, his moderate indeterminism yields no comfort to those, such as James and other process philosophers, hoping to find room for the mental liberation of free will (see for example Santayana's reply to Charles Hartshorne in *The Philosophy of George Santayana*, pp. 591–593). On Santayana's view of spirit, any mental feelings of power and control simply register developments happening in the psyche. The psyche deliberates and chooses by purely mechanical processes, and the feelings that report these processes have no role.

While disagreeing with James about whether spirit has consequences for the course of the physical world, Santayana did appreciate James's theory of belief. Santayana could never accept James's pragmatic theory of truth, but James's psychological views on belief are repeated in Santayana's notion of "animal faith." Animal faith is the natural, automatic, and common-sense belief in the knowable external world of things in the environment (Sprigge, pp. 52–54). For both James and Santayana, the common-sense world of ordinary belief should be the common ground and starting-point for the various metaphysical standpoints of idealism, representational dualism, realism, materialism, and the like. The common-sense world certainly is the starting point of all people whom metaphysicians would convert to their standpoint. In his 1890 *The Principles of Psychology*, particularly chap. 21 on "The Perception of Reality," James argues that the distinction between an external object and a perception of an object has no place in ordinary life. We simply experience the world as a surrounding world of objects to be interacted

with. We certainly do not think that we are only experiencing the mental ideas within our private minds, for example; skepticism about external things is not a natural attitude. In the course of experience, we will learn that some experiences cannot be trusted, but this doubt is learned doubt: we learn to doubt some experiences only because other known experiences are taken as more reliable. Skepticism towards all but the most certain experiences, of the sort that results from requiring too high a standard of proof, is hardly the natural attitude of intelligence. Like Peirce before him, James held that universal doubt is impossible, and that knowledge is simply the practical competence of everyday active life. Ir (1923), Santayana agrees with James that the foundation of knowledge is only naïve animal faith, not rational certainty. This practical faith operates primarily at the behavioral level of the animal psyche, which explains why this faith typically need never rise even to the level of intuition; we don't even realize, much less enunciate as an explicit proposition, how much of our environment we take for granted.

Santayana's theory of animal faith is offered as an appropriate starting place for philosophical reflection. This tactic directly challenges most of modern philosophy's preference for starting from an alleged certainty about the immediate contents of one's m

Santayana's confidence in the realm of matter, and his estimate of its general characters, is predicated upon animal faith. Strictly speaking, the realm of spirit has no direct acquaintance with matter – Santayana's naïve realism of animal faith is quite different from the naive realism of other epistemologists who adopted that label for their own empiricisms. Several of these naïve realists, such as Ralph Barton Perry, followed James's view that objects of knowledge are directly present in experience, rather than lying behind a veil of representations. On Santayana's terms, experience is of the realm of spirit, however. For Santayana, we do not have faith in the world of external objects because we directly perceive them. Quite the reverse: we take our perceptions of things to be the things themselves only because the psyche confidently engages external objects. A little reflection is all that is needed, for Santayana, to dispel the illusion raised by this sort of naïve realism. Only a "conventional" psychology would suppose that the organism's reactions to external objects are somehow identical, either ontologically or epistemologically, with any traits of the objects themselves. The psyche's adaptations to the surrounding world are within the psyche itself; external objects are external precisely because their properties are their own. Furthermore, the psyche's adaptations could not be supposed to "copy" any properties of external objects since such a coincidence would be quite unnecessary, and probably detrimental to, the proper functioning of the psyche.

Even more misguided from Santayana's viewpoint is naïve realism's false notion that mental intuitions of spirit could be ontologically or epistemically identical with features of external objects. Where intuitions are symbols of

external things, it is the nature of symbol that it does *not* crudely copy its object's features. Like Peirce, Santayana takes symbols of reality to have a triadic nature, because three things are involved: a repeatable mental intuition, a habit of the psyche, and an external object. So long as the relations are regular and dependable, the specific character of the mental intuition could be anything. For example, a rose can be a symbol of love without itself possessing any properties of love. The way that psyche's habits produce symbols is contingent (though not "conventional" as if decided by a group's decisions) but not random: Santayana holds that patterns of spirit's ideas will track psyche's patterns of habits as psyche interacts with external objects. Only in this sense does mind "correspond" first with psyche, through psyche, with external objects.

The mind's symbols for external reality, from our perceptions of the colors of things to our theories of the molecular structures of things, cannot be said to match those things' properties. That an essence intuited by spirit should precisely duplicate an essence pertaining to an external thing would simply be an extraordinary coincidence of no significance whatsoever. Only in vague generalities, conveyed by animal faith itself, does spirit possess pictures of the realm of matter: its actively powerful nature, its multiplicity and diversity, and its relentlessness. Philosophical theorizing cannot come to possess specific truths about details of the material realm, and science suffers from the same disability since its own theories cannot aspire to be literal truths. Santayana permitted his philosophy to be labeled as a "critical realism" because his confidence in the external material world was matched by his demand that only a critical philosophy could properly distinguish the mind from the material world. His contribution to the collective volume *Essays in Critical Realism* (1920), titled "Three Proofs of Realism," refused to suppose, as some of his co-authors did, that some essences in spirit represent external physical properties. These other critical realists embraced representationalism in order to account for truth, and appreciated Santayana's notion of essence because an essence could be instantiated simultaneously in both an external object and in consciousness. Santayana's essences are simply any properties or traits or forms that a thing could possibly have; not only the things that have existed and will exist in this world, but in any possible world (Sprigge, pp. 92–94). Essences can be exemplified by material things or spiritual ideas; our own acquaintance with essences comes through the medium of ideas, concepts, propositional terms, and the like, but essences must not be confused with any of those exemplifications. An essence is a universal because it is endlessly repeatable; an essence is also uniquely particular since the slightest difference to an essence results in a different essence. Though eternal and unchanging, essences do not exist; they can be given in intuition but are never the object of any sort of knowledge. Rather, essences are the very terms by which knowledge can be formulated. For Santayana, knowledge does not aim

at reproducing in spirit the essences of matter, which set him apart from other critical realists of his day.

It would be incorrect to suppose that Santayana intended to embrace a thorough-going skepticism towards knowledge and scientific theorizing. Since spirit's patterns of thought are deliberately organized to take advantage of habitual patterns of psyche's conduct, thought can satisfactorily express, without mirroring, the consequences of the organism's dealings with nature. Santayana did not develop a philosophy of science. However, he did clearly hold that science, like any practical knowledge, does not aim at presenting things are they truly are in themselves, but rather science aims at a systematic method of anticipating the consequences of various modes of interacting with things. Santayana was a scientific realist, therefore, even while he abandoned correspondence, since science is about the going-on in nature and tracks them with fair success. This view of science's instrumental nature is quite pragmatic, and if Santayana had cared to write more about science, greater appreciation by other pragmatists might have been forthcoming.

While some pragmatists did notice and appreciate Santayana's defenses of realism against idealism and his portrayal of human beings as intelligent animals struggling in a precarious world, several major points of disagreement were also obvious to all. First and foremost, pragmatists like John Dewey were highly suspicious of Santayana's essences and his predilection for passively and aesthetically contemplating them. Santayana believed that he was safeguarding the moral life by providing for a way to occasionally disengage from the practical life. Such disengagement is possible because the mind can withdraw the "intent" ordinarily infusing intuition, leaving behind a passive absorption in the essences. Rejecting James's and Royce's notion that ideas are always "plans of action," Santayana held that the mind's distinctively higher power is precisely the ability to suspend any plans. Santayana well understood that such disengagement from the purposive life directly contradicted the pragmatists' demand that the moral life could only be practical. Welcoming the opportunity to stand opposed to the lingering Puritanism of James, Royce, and Dewey, Santayana posed his philosophy as a path to liberation, a liberation from the wearying moral life.

By recasting the essence of the moral life, Santayana's version of pragmatism offered a genuine third alternative to James and Royce (Levinson, pp. 87–95). Santayana agreed with James that actual human desires and interests are the origin of value, and that reason attempts to maximize various kinds of harmonies of these personal aims. In *The Life of Reason*, Santayana looked to morality as a rational practice to harmonize among the competing interests of society members, yet he refused to search for any *a priori* ethical principles to establish universal order. Harmonies are the goal of life; but humanity should not search for some supreme harmony valid for all. By locating in social practices and institutions the rational morality needed for social order,

Santayana pointed towards cultural pluralism and relativism. However, this relativism is only *philosophical*; Santayana never recommends the disintegrating attitude of relativism towards one's own cultural norms and religion. Contradicting Royce, Santayana denied that some absolute rational standard of knowledge or morality is required to make sense of the diversity of human projects. Reason cannot dictate which essences provide the path to spiritual perfection. And while James was searching for a common mystical core to all religions, Santayana might have been the greater pragmatist when he only found a common function: to provide a space for imaginative contemplation in the face of inevitable failure and disaster for human projects. This imaginative contemplation of withdrawal is the path to the highest liberation attainable.

It is not clear whether Santayana recommends spiritual adoration of eternal ideals for everyone, as if the contemplative religious life is the best form of life. However, it is clear that religion can provide relief and happiness for many. So long as religion does not pass into superstition by demanding for its ideals a reality to compete with practical reality, religion is part of the rational life for Santayana. Pragmatists like Dewey additionally require that religion become fully practical by positively contributing to human endeavors, and demand that religion be continually reformed as a means to this end. For Santayana, religion's practical consequences are only side effects; ideals by definition cannot be criticized for being impractical. It is precisely their aloofness from the bustle of earthly life which attracts the contemplation of those desiring peace.

Santayana's praise for aesthetic and religious delight in contemplating essences was an anathema to pragmatists. Most pragmatists deplored the realm of essence as hypostatisations of mental ideas taken as static and self-sufficient. Unable to resist concentrating their attack upon essences, pragmatists wasted much effort by failing to understand them. Pragmatists use essences like any other conscious and thinking creatures. The pragmatist objection should instead have been more carefully aimed at Santayana's estimation of the value of contemplating essences for their own sake. By finding values embedded in experiences of actual things, pragmatism offered an alternative theory of ideals. Dewey, for example, argued that any religion that encourages resignation and surrender to prevailing conditions only slows progress for human happiness in the long run. Little constructive debate took place on this issue, unfortunately, despite the opportunities for fruitful comparison of views (see Levinson, pp. 199–203, 221–226).

Rebutting the charge of hypostatisation to find essences, Santayana always insisted that "nothing given exists." As much as Santayana deplored the pragmatists' reliance on experience in epistemology, he had even greater concerns over epistemologists returning to foundationalism by searching for indubitable sense-data. Some critics thought that Santayana's doctrine of

essence offered an alliance with foundationalism, but these critics failed to understand Santayana's tactics in *Scepticism and Animal Faith* and later works. According to Santayana, the more refined and pure one's sense-datum, the closer one approaches to a single essence. As possibility of error diminishes by narrowing one's attention upon some lone intuition, such as a shape or a color or sound, meanings are stripped away until only one essence dominates the intuition. The remaining essence is relationless, and so no inference can use it and no reality can be inferred from it. The essence by itself lacks existence and has no capacity to confer existence on anything else. A sense-datum therefore becomes "certain" only at the price of becoming impotent to lead back to any other reality. The foundationalist's quest for certainty thus only leads down a dead-end to a skeptical solipsism of the present moment. Santayana has no alternative path to certain knowledge to offer, and so he only can offer a different sort of skepticism: the fallible knowledge that arises from animal faith. Santayana is content to call himself a skeptic, not because we ought to refrain from believing, but rather because we only have beliefs of varying degrees of reliability short of certainty. Our body of beliefs will grow and change as we compare them to each other, and the more reliable beliefs earn the title of "knowledge." For Santayana, absolute truth pertains to the actual states of all reality, but this absolute truth is not available to human beings (see Sprigge, pp. 163–175, for discussion of Santayana's notion of truth). While useless for practical knowledge, absolute truth cannot be thereby condemned, and pragmatists should not make confusing identifications of usefulness and truth.

Santayana uses the term "experience" almost as frequently as any empiricist of his era, and he could not be accused of a priori rationalism. His credentials as an empiricist may be questioned, however. Empiricists claim that all knowledge arises from experience, where experience is understood phenomenally: the objects and events as experienced by the knower. Some empiricists go farther and claim that knowledge never goes beyond the knower's experiences; this position is phenomenalism and just a step away from solipsism. Indeed, Santayana's epistemology would be phenomenalism, except for his claim that many experiences are genuine symbols of external events that never appear in experience. Representationalist empiricism does not differ greatly from Santayana's theory, perhaps only adding that some experiences might copy features of external objects. Other empiricists, such as Peirce, James, and Dewey, hold that many experiences are directly and immediately of external objects, in the sense that experience includes some of their features. Santayana rejects this sort of immediate experience, finding it unwarranted in light of the *relativity* of experience and knowledge: experience and knowledge results from the perceiving organism's interactions with nature, and could not possible be expected to enjoy a perfect transmission of external properties which are instead *absolute*.

Santayana offers various "proofs" of realism that undertake to showing that it is rational to believe that there is an inaccessible and largely unknowable material realm beyond all experience. Unfortunately, these proofs suffer from two main problems. First, Santayana appeals to ordinary common-sense experience to certify that we believe in the material world, but what sense of experience does he mean here? He cannot be talking about experience as events within spirit itself, since according to his philosophy we cannot infer anything about reality from the contemplation of intuited essences. Of course, Santayana wants us to understand that some patterns of intuitions are genuine knowledge of external events, but such a supposition would just beg the question. Perhaps Santayana is appealing instead to the experience of the psyche; that sort of experience would be more consistent with his appeals to animal faith. However, to believe that the psyche experiences is to already believe that the material realm exists, which again begs the question. Second, Santayana's appeals to ordinary common-sense experience are not argumentatively superior to the standpoint of immediate empiricists like James and Dewey, who similarly appeal to ordinary common-sense experience to defend their view that experience is directly of its objects. Indeed, immediate empiricists would have the upper hand in this debate, since Santayana has already eloquently argued that animal faith dogmatically accepts the reality of things in experience. Santayana is in a weak position because he tries to appeal to common-sense to infer that we easily believe in an unknowable transcendent realm of mysterious matter. No one of sound common-sense actually does this, of course.

Ultimately, it is Santayana's conviction that the realm of ultimate power and responsibility must have its own intrinsic properties and traits which determines his conviction that both phenomenal experience and knowledge must forever be inadequate to, and hence quite separate from, this realm of matter. Since matter's intrinsic properties entirely capture its reality, and since spirit can never intuit these properties, spirit and matter must be quite unlike each other. This logic is evident in Santayana's debates with Dewey after the publication of Dewey's *Experience and Nature* in 1925, especially Santayana's article "Dewey's Naturalistic Metaphysics," in this volume. Santayana accuses Dewey of grounding his pragmatism on arbitrary phenomenalism, because human involvement in creating experience dooms experience to only capture the "foreground" of nature (see Levinson, pp. 218–221). Dewey accepts the relativity of knowledge; thus must he not admit that his empiricism is shallow phenomenalism? In Dewey's defense, his philosophy holds that relational properties as just as real as intrinsic properties. If experience be composed of mostly relational properties (such as color, which is the result of external light stimulating the nervous system), then such properties are good candidates for really being of nature, and not merely being trapped inside a private consciousness. For Dewey, experience can thus be a field of nature that

happens to include a perceiver. Color, for example, is not a property of my nervous system or my mind, but rather a property of the entire system of "light–reflective object–organism." Experience therefore is not superficial, but rather has depth into nature, and that depth can be extended by improved instrumentation and theoretical knowledge. Of course nature always has its own properties that do not depend on systems that include perceivers, but even while those properties are a goal of scientific knowledge, they do not have any sort of superior reality to other relational properties that do include perceivers. Dewey's empiricism attempts to overcome Cartesian dualism by healing the divide between experience and nature, while Santayana's a priori convictions about matter seemed to Dewey to lead back toward dualism.

Santayana could well appreciate that James and Dewey, like Royce and Peirce, would be unable to resist appealing to idealism to overcome ontological dualism. If only nature would so easily conform to our pleasant and useful experiences! Unfortunately for idealism, spirit finds itself in a world not of its making. Spirit needs matter but matter does not need spirit; this ultimate tragedy is also spirit's opportunity for its greatest triumph. Spirit can suspend effort and simply enjoy the unchanging and eternal essences. The most useless thing, beauty, is the spirit's salvation.

C. I. Lewis: The Rationality of an Empiricist

Lewis never strayed far from epistemology during his career. Satisfied with the position shared by James and Royce (and most of Anglo-American philosophy since Locke), that human experience is the base from which reason starts out and must return to, Lewis pursued the mind's role in creating knowledge. He had no illusions about his consuming devotion to that field of philosophy called epistemology. Lewis confesses to lacking genius sufficient for speculative metaphysics in his "Replies to Critics" (*The Philosophy of C. I. Lewis*, p. 655) but soon clarifies that "whenever I make attempt on metaphysics, it always comes out epistemology" (p. 663). The primary reason why Lewis did not attempt metaphysics apart from epistemology is because he held that philosophy does not increase knowledge of reality, but only investigates the methods by which knowledge is possible. "It is not the business of philosophy, as it is of the natural sciences, to add to the sum total of phenomena with which men are acquainted. Philosophy is concerned with what is already familiar" (*Mind and the World Order*, pp. 2–3). Metaphysics is only "the problem of the categories" by which we ascribe reality (pp. 10–11). Lewis's two great works of philosophy are *Mind and the World-Order* (1929) and *An Analysis of Knowledge and Valuation* (1946); his moral theory is presented in *The Ground and Nature of the Right* (1955).

Lewis never made any apologies for grounding his philosophy on experience, even as the tide of philosophical fashion turned against him.

Like John Dewey, Lewis witnessed how the initial phenomenalism of logical positivism, somewhat congenial to his own standpoint, evolved into a confident physicalism during the 1940s and early 1950s. Lewis rebuffed this new physicalist empiricism and its associated "linguistic turn," as it tried to eliminate reference to experience with appeals to pieces of language such as observation sentences, or to modes of behavior. "To my jaundiced eye, this behaviorist dialect is a somewhat muscovite methodology for disallowing any mention of the obvious facts of life which they perversely refuse to recognize" (p. 664). A philosopher like Lewis, anxious to integrate meanings, norms, and values with modern science, could not respect physicalism. His rejection of physicalist empiricism must not be construed as any sort of disrespect for science itself. Lewis celebrated science's protean character of continually making and re-making ever more imaginative theories. However, science is unstable ground for erecting permanent decisions about the ultimate traits of reality. Lewis recognized early that the very mutability of theories might seem an opportunity to replace experience-talk with some other language-scheme. He warns those who would in Orwellian fashion eliminate the thing by eliminating talk about the thing: "...let us not abdicate to those crypto-materialists who think that if we can be prevented from using any word which applies to immediate experience, or any factor in it, we may eventually forget that there is such a thing" (p. 665).

Lewis began his career as an idealist under Royce's tutelage. Proficient in idealism's tactics for transcending the immediate experience of the present moment, Lewis argued in his dissertation that the real object in experience is always conceived as having a reality that extends beyond its momentary presentation to a knower. Perceiving a thing as a real object imaginatively categorizes it as a certain type of thing having further related properties capable of investigation and verification from other perspectives and under certain conditions. For example, perceiving the moon is the perception of a spherical object, conceived as having a far side that could also be observed under some other specifiable conditions. Lewis, following Royce's lead, regards conceptions as purposive, in a double sense: (1) the transition from a perception to a conception involves the mind's voluntary role because the mind chooses how to categorize a perception as a perception of a certain kind of object; (2) the conception of a certain thing always involves that thing's further properties that could be revealed in future possible experience if the perceiver decides to pursue their observation. Lewis further stipulates that (3) the real object always has observable properties that outrun finite possible experience, so that finite creatures will never completely know an object, and that (4) no completely unknowable object could be conceived as real. Lewis retained these four principles in some form during the rest of his career, regarding them as the foundations of an epistemology which integrates key insights of pragmatism, realism, and idealism.

Lewis made an early and permanent departure from Royce's absolute idealism by refusing to follow Royce's arguments that we must conceive the real object as ultimately knowable by an actually existing perfect and absolute mind. It is not necessary to regard the absolute mind as actually existing; it is sufficient to regard the real object as hypothetically knowable in some idealized infinite process. Knowledge is ideal in the sense that it aims at an ideal of reason, and not in the sense that an ideal mind actually possesses perfect knowledge already. Here, Lewis follows Kant rather than Royce (Murphey, pp. 59–60) by regarding such an idealized knowledge as a regulative ideal rather than a constituative ideal. This stance against Royce only returns Lewis to the general standpoint already occupied by Charles Peirce, who had defined scientific truth as that knowable by an idealized community of inquirers having taken inquiry to its furthest possible extent. In the early 1920s Lewis took advantage of his access to Peirce's papers at Harvard to discover his connections with Peirce's pragmatism, and also to reconsider the legacies of James and Royce. In his "Autobiography" Lewis relates how this familiar ferment settled into his first great work, *Mind and the World Order*, where he classified his philosophy as "conceptual pragmatism" (*The Philosophy of C. I. Lewis*, p. 16–17). However, Lewis also knew where he disagreed with James and Dewey on truth, since they were content to label as truths the piecemeal and finite experiences of one's predictions and verifications. While those pragmatists made truth seem too easy, the New Realists such as his teacher and colleague Ralph Barton Perry made reality too remote. By opposing idealism with their contention that some realities may exist completely beyond any possible experience, they seemed to demand the conception of something transcendental that cannot be conceived. Such an unknowable *ding-an-sich* no longer had a respectable place in philosophy, Lewis was convinced. This position on the unknowable informs Lewis's accusation in "Professor Santayana and Idealism" that Santayana likewise demands belief in an inconceivable realm of matter. Since Santayana holds that credit goes to the essences for supplying intelligibility to material things, matter itself must be conceived as utterly formless and indistinct, an impossible mental feat.

By aligning his epistemology with the pragmatist view that the mind actively and purposively organizes the flow of experience, Lewis creatively developed his broadly Kantian standpoint. Complicating Lewis's efforts was his conviction, shared by most of his contemporaries, that the category of the synthetic a priori is empty because the a priori coincides with the analytic. It additionally seemed obvious to Lewis that a mind that can impose its schema on new experience must be a mind wielding organizing categoreal schemes impervious to contact with that new experience. If organizing schemes are partially modified by new experiences upon meeting, they would soon fail to impose any consistent and predictable patterns on experience. Because

experience evidently displays consistent and fairly predictable patterns, organizing schemes of categories must be independent of experience: they are a priori, and hence they also must be analytic. This position on the mind's powers presented Lewis with a major difficulty, wide shared among neo-Kantians, because analytic a priori propositions seem so platonically aloof from sensation. In what manner does the mind decide how to apply analytic a priori propositions to the flow of experience?

Lewis's answer lies in his pragmatic notion of the mind's voluntary application of a concept to a presentation. The mind imposes a conceptual interpretation on some given portion of experience, and can then connect that portion with other portions (past, present, or future) because that concept is already analytically connected to other concepts. To refer again to the example of seeing the moon, if the mind categorizes a portion of qualitative experience (the "given") as "the moon," then the mind already has a secure path from "moon" to "spherical object" to "facing curved side plus hidden curved side" to "hidden side could be observed from a position behind it." The final stage in this example leads to a future possible experience. The full process from initial categorization to final verification is fallible: although the logical connections between the concepts are analytic a priori, they do not dictate the outcome of any verification attempt. Furthermore, if falsification occurs instead, the rational mind should revise its conception of the explored object, but no modification to the conceptual connections need occur. Two additional points must be emphasized. First, Lewis clearly states that the given is never isolatable and detectable in ordinary experience: we never perceive the given in isolation from all concepts. Rather, ordinary experiences are fused unities of givenness and conceptualization, because the mind busily categorizes everything to at least a minimum degree where its attention is focused. Like Peirce's instances of qualitative firstness, nearly pure givens may only reside at the very margins and fringes of consciousness. The effort of attention and abstraction required for "discovering" a pure given in experience gives away the game: that allegedly pure given is instead a careful product of rigid conceptualization and hence is still the object of fallible judgment. Even an example like "this patch of red here and now" displays conceptualization and categorization. Second, because the given is a constituative element of experience, no knowledge of the given is possible. Lewis is a sophisticated post-Kantian empiricist, and not a sensationalist or sense-data empiricist seeking indubitable foundations in experience to ground all other knowledge.

Some further discussion of Lewis's controversial notion of the given is required here. Lewis's confidence that there is an independent element of givenness in experience has long been comforting to empiricists. When Lewis was beginning his career, many idealists (including Royce) regarded this notion of givenness as a serious threat, for they characteristically denied the reality of anything having origins independent from all experience. How

could an empiricist prove the existence of this givenness? By explaining that the given cannot be an object of knowledge, Lewis placed himself in a vulnerable position. Idealists easily dismissed such givenness as unknowable and hence illusory; mind, they inferred, must accordingly be somehow responsible for both the content and conceptualization of all experience. Lacking any forthright knowledge of the given, how could Lewis argue for its reality? Lewis constructed an argument from the pragmatic principles about the mind's own powers. Precisely because there are many ways to organize experience, we grasp that the mind's operations are variable. Lewis's insight in the 1910s that even logical systems are free constructions of the mind, each just as "logical" as the next (for a discussion of Lewis on alternative logics and possible worlds, see Murphey, pp. 83–102) heightened his belief that conceptual systems do not automatically apply to reality. Yet we simultaneously grasp that the mind encounters elements in experience, the "given," not of its own creation. The mind works with raw materials that are not infinitely plastic, but rather resist to some degree. The experience of shock and surprise demonstrates that the mind does not have complete control over experience.

Since the mind cannot fully anticipate the onrushing flow of experience, but instead has diverse systems of concepts to alternatively apply as purposes warrant, we experience our intellectual efforts as interacting with something not of our own creation. This supplies knowledge's objectivity: our theories are continually tested against reality. Kant earnestly defended synthetic a priori judgments as his best answer to the question of how successful prediction of future experience is possible. Lewis's alternative explanation of successful prediction is instead an account of the mind's gradual trial-and error organization of experience that preserves successes over time. To the ultimate question, why is reality intelligible at all, Lewis offers no answer. Apparently new experience is not so chaotically unlike past experience as to completely overwhelm our current categories, but the reason for this is obscure; we still live in a somewhat Humean universe. For Lewis, it is epistemology's task to study the mind's role in knowledge, and not to speculate upon ultimate cosmological matters beyond knowledge's reach.

Lewis did not develop a complete philosophy of science, remaining focused on the general features of empirical knowledge. He did defend a type of scientific realism, offer a pragmatic justification for induction in *Mind and the World-Order*, and sketched a theory of probability in both *Mind and the World-Order* and *An Analysis of Knowledge and Valuation* (on induction and probability, see Murphey, pp. 161–168, 281–290). Lewis's departure from the typical anti-realism of empiricism deserves extended comment here. Lewis argued that it is possible to acquire (fallible) knowledge of non-observable entities postulated by science. Against all positivisms, this position on non-observables endorses warranted belief in the reality of such non-

observables, and hence for Lewis realistic conceptions of those objects can be rational. When science postulates an entity too small (or too large, or too distant, etc.) to be detectable in experience even if aided by instruments, Lewis denied that the meaning of that entity is reducible to its effects. It is sufficient that the conception of the entity is objective: that it is conceived as an object having specifiable properties and effects under certain conditions, permitting the imagination to conceive how it could be observed (even if we cannot imagine how to make such observation technologically possible). Lewis in effect endorses scientific realism towards those entities which scientists conceive as objects having their own properties and effects on other objects. Against logical positivism, Lewis accordingly finds that a concept like "electron" has a quite clear meaning, despite the fact that no reduction to actual observations has been accomplished.

A common tactic of anti-realistic philosophies of science has been to argue that no probability of correctness can be assigned to any theory about unobservables (which use what Lewis called "non-terminating judgments" about these real objects), because a potentially infinite number of alternative hypotheses might be constructed to explain the same finite set of data (which are expressed in what Lewis termed "terminating judgments" that rest on the given, similar to "observation sentences"). Lewis did not adequately deal with this anti-realist challenge; the complexities of what would now be called "abductive inference" eluded him. He took for granted the questionable notion that successful predictions increased the probability of a hypothesis. Popper's idea that special sorts of confirmations, such as outcomes of crucial experiments in which rival theories predict contrary experimental consequences, does not appear in Lewis's work.

Empirical knowledge is viewed by Lewis as a system of interrelated conceptual systems which are all used in some way to guide our predictions about the consequences of our deliberate actions. Lewis held that objectivity is achieved when these systems are evaluated in light of their capacity to provide such practical guidance into the future. Lewis recognized (as did Peirce, James, Dewey, and Santayana) that scientific reason is an evolving spectacle of competing and mutating theoretical systems attempting to increase the coherence and predictability of lived experience. Lewis followed this pragmatic line of thought to the conclusion that analytic propositions may also be *a posteriori* because experience can (indirectly) show conceptual relations to be inadequate to reality. Relations between concepts can be analytically applied as rigid organizers of experience and under such conditions they could not be *a posteriori*. However, under other circumstances, alternative systems of conceptual relations can be applied, by individuals but more usually by communities. For example, a scientific community can make such decisions, and in this sense concepts and conceptual relations can be conventional. Under pressure from unexpected experience, a scientific

community may pragmatically re-organize a theoretical system of concepts, abandoning and replacing some analytic propositions in the process.

> ... the whole body of our conceptual interpretations form a sort of hierarchy or pyramid with the most comprehensive, such as those of logic, at the top, and the least general, such as "swans" etc., at the bottom; that with this complex system of interrelated concepts, we approach particular experiences and attempt to fit them, somewhere and somehow, into its preformed patterns. Persistent failure leads to readjustment; the applicability of certain concepts to experiences of some particular sort is abandoned, and some other conceptual pattern is brought forward for application. The higher up a concept stands in our pyramid, the more reluctant we are to disturb it, because the more radical and far-reaching the results will be if we abandon the application of it in some particular fashion. (*Mind and the World-Order*, pp. 305–306)

Lewis's portrait of scientific progress is quite similar to Quine's conclusion to his story of the "web of belief": even a theoretical web's core propositions like scientific definitions of basic terms, axioms of logic, or premises of mathematics might require modification or replacement if more accurate empirical predictions are secured as a result. But the fact that such core propositions are indirectly answerable to future experience does not mean that they are actually synthetic. As Lewis emphasized, whether a proposition is analytic or synthetic, and hence whether it may be a priori or a posteriori, depends on its functional treatment by a community. When Quine doubts in "Two Dogmas of Empiricism" (1951) whether any analytic proposition can be once and forever identified, he only confirms by a separate route Lewis's own preference for understanding propositions within community contexts. Nevertheless, Lewis was among the first to fully realize that the tremendous impact of Quine's attack on the analytic/synthetic (and the extensionalist logic which Lewis had been combating for decades) was devastating for his own epistemological project.

Lewis long supposed that the combination of his idealized approach to knowledge, his rejection of transcendental realism, and his antipathy towards materialism consequently forbid any entanglement with naturalism. In the hands of most self-proclaimed "naturalists" up to that era, naturalism stood for elevating science to the position of dictating all of reality, and was little more than an alternative term for materialism. Like the physicalism of more contemporary philosophy, naturalism demanded that an allegedly real entity be either reducible in principle to some entity knowable by science, or eliminated as delusion and error. The objects of religious faith, the ideals of the moral life, the values that motivate conduct, and the experiences of the mind, only mentioning prominent targets of naturalism, must be redescribable as

something within nature or be banished. Lewis was never a naturalist in this sense. He did attempt to show, much in the manner of Dewey, that values are neither purely subjective nor independently objective (Murphey, pp. 290–312). It is necessary to first analyze the role that value judgments play in our intellectual lives. Because value judgments are predictions about the experienced consequences of our deliberate interactions with the world and others, they are of a kind with all empirical judgments, and hence their objectivity resides in their capability for being tested: value judgments can be warranted or falsified. There is another sense in which value judgments are "subjective" where different people are interested in pursuing different kinds of experiences, but this is quite distinct sense of "subjective" at issue and cannot affect their empirical status. As he began to realize that values can be treated like other empirical judgments, Lewis came to describe his position as naturalistic, to distinguish his view from the emotivism approach to values and ethics which had abandoned hope for any empirical treatment of value judgments.

Writings by George Santayana

HOW THOUGHT IS PRACTICAL

George Santayana. "How Thought is Practical." *The Life of Reason*, vol. 1: *Reason in Common Sense* (New York: Charles Scribner's Sons, 1905), chap. 9, pp. 205–235.

Nothing is more natural or more congruous with all the analogies of experience than that animals should feel and think. The relation of mind to body, of reason to nature, seems to be actually this: when bodies have reached a certain complexity and vital equilibrium, a sense begins to inhabit them which is focussed upon the preservation of that body and on its reproduction. This sense, as it becomes reflective and expressive of physical welfare, points more and more to its own persistence and harmony, and generates the Life of Reason. Nature is reason's basis and theme; reason is nature's consciousness; and, from the point of view of that consciousness when it has arisen, reason is also nature's justification and goal.

To separate things so closely bound together as are mind and body, reason and nature, is consequently a violent and artificial divorce, and a man of judgment will instinctively discredit any philosophy in which it is decreed. But to avoid divorce it is well first to avoid unnatural unions, and not to attribute to our two elements, which must be partners for life, relations repugnant to their respective natures and offices. Now the body is an instrument, the mind its function, the witness and reward of its operation. Mind is the body's entelechy, a value which accrues to the body when it has reached a certain perfection, of which it would be a pity, so to speak, that it should remain unconscious; so that while the body feeds the mind the mind perfects the body, lifting it and all its natural relations and impulses into the moral world, into the sphere of interests and ideas.

No connection could be closer than this reciprocal involution, as nature and life reveal it; but the connection is natural, not dialectical. The union will be denaturalised and, so far as philosophy goes, actually destroyed, if we seek to carry it on into logical equivalence. If we isolate the terms mind and body and study the inward implications of each apart, we shall never discover the other. That matter cannot, by transposition of its particles, *become* what we call consciousness, is an admitted truth; that mind cannot *become* its own occasions or determine its own march, though it be a truth not recognised by all philosophers, is in itself no less obvious. Matter, dialectically studied, makes consciousness seem a superfluous and unaccountable addendum;

mind, studied in the same way, makes nature an embarrassing idea, a figment which ought to be subservient to conscious aims and perfectly transparent, but which remains opaque and overwhelming. In order to escape these sophistications, it suffices to revert to immediate observation and state the question in its proper terms: nature lives, and perception is a private echo and response to ambient motions. The soul is the voice of the body's interests; in watching them a man defines the world that sustains him and that conditions all his satisfactions. In discerning his origin he christens Nature by the eloquent name of mother, under which title she enters the universe of discourse. Simultaneously he discerns his own existence and marks off the inner region of his dreams. And it behooves him not to obliterate these discoveries. By trying to give his mind false points of attachment in nature he would disfigure not only nature but also that reason which is so much the essence of his life.

Consciousness, then, is the expression of bodily life and the seat of all its values. Its place in the natural world is like that of its own ideal products, art, religion, or science; it translates natural relations into synthetic and ideal symbols by which things are interpreted with reference to the interests of consciousness itself. This representation is also an existence and has its place along with all other existences in the bosom of nature. In this sense its connection with its organs, and with all that affects the body or that the body affects, is a natural connection. If the word cause did not suggest dialectical bonds we might innocently say that thought was a link in the chain of natural causes. It is at least a link in the chain of natural events; for it has determinate antecedents in the brain and senses and determinate consequents in actions and words. But this dependence and this efficacy have nothing logical about them; they are habitual collocations in the world, like lightning and thunder. A more minute inspection of psycho-physical processes, were it practicable, would doubtless disclose undreamed of complexities and harmonies in them; the mathematical and dynamic relations of stimulus and sensation might perhaps be formulated with precision. But the terms used in the equation, their quality and inward habit, would always remain data which the naturalist would have to assume after having learned them by inspection. Movement could never be deduced dialectically or graphically from thought nor thought from movement. Indeed no natural relation is in a different case. Neither gravity, nor chemical reaction, nor life and reproduction, nor time, space, and motion themselves are logically deducible, nor intelligible in terms of their limits. The phenomena have to be accepted at their face value and allowed to retain a certain empirical complexity; otherwise the seed of all science is sterilised and calculation cannot proceed for want of discernible and pregnant elements.

How fine nature's habits may be, where repetition begins, and down to what depth a mathematical treatment can penetrate, is a question for the

natural sciences to solve. Whether consciousness, for instance, accompanies vegetative life, or even all motion, is a point to be decided solely by empirical analogy. When the exact physical conditions of thought are discovered in man, we may infer how far thought is diffused through the universe, for it will be coextensive with the conditions it will have been shown to have. Now, in a very rough way, we know already what these conditions are. They are first the existence of an organic body and then its possession of adaptable instincts, of instincts that can be modified by experience. This capacity is what an observer calls intelligence; docility is the observable half of reason. When an animal winces at a blow and readjusts his pose, we say he feels; and we say he thinks when we see him brooding over his impressions, and find him launching into a new course of action after a silent decoction of his potential impulses. Conversely, when observation covers both the mental and the physical process, that is, in our own experience, we find that felt impulses, the conceived objects for which they make, and the values they determine are all correlated with animal instincts and external impressions. A desire is the inward sign of a physical proclivity to act, an image in sense is the sign in most cases of some material object in the environment and always, we may presume, of some cerebral change. The brain seems to simmer like a caldron in which all sorts of matters are perpetually transforming themselves into all sorts of shapes. When this cerebral reorganisation is pertinent to the external situation and renders the man, when he resumes action, more a master of his world, the accompanying thought is said to be practical; for it brings a consciousness of power and an earnest of success.

Cerebral processes are of course largely hypothetical. Theory suggests their existence, and experience can verify that theory only in an indirect and imperfect manner. The addition of a physical substratum to all thinking is only a scientific expedient, a hypothesis expressing the faith that nature is mechanically intelligible even beyond the reaches of minute verification. The accompanying consciousness, on the other hand, is something intimately felt by each man in his own person; it is a portion of crude and immediate experience. That it accompanies changes in his body and in the world is not an inference for him but a datum. But when crude experience is somewhat refined and the soul, at first mingled with every image, finds that it inhabits only her private body, to whose fortunes hers are altogether wedded, we begin to imagine that we know the cosmos at large better than the spirit; for beyond the narrow limits of our own person only the material phase of things is open to our observation. To add a mental phase to every part and motion of the cosmos is then seen to be an audacious fancy. It violates all empirical analogy, for the phenomenon which feeling accompanies in crude experience is not mere material existence, but reactive organisation and docility.

The limits set to observation, however, render the mental and material spheres far from coincident, and even in a rough way mutually supple-

mentary, so that human reflection has fallen into a habit of interlarding them. The world, instead of being a living body, a natural system with moral functions, has seemed to be a bisectible hybrid, half material and half mental, the clumsy conjunction of an automaton with a ghost. These phases, taken in their abstraction, as they first forced themselves on human attention, have been taken for independent and separable facts. Experience, remaining in both provinces quite sensuous and superficial, has accordingly been allowed to link this purely mental event with that purely mechanical one. The linkage is practically not deceptive, because mental transformations are indeed signs of changes in bodies; and so long as a cause is defined merely as a sign, mental and physical changes may truly be said to cause one another. But so soon as this form of augury tries to overcome its crude empiricism and to establish phenomenal laws, the mental factor has to fall out of the efficient process and be represented there by what, upon accurate examination, it is seen to be really the sign of – I mean by some physiological event.

If philosophers of the Cartesian school had taken to heart, as the German transcendentalists did, the *cogito ergo sum* of their master, and had considered that a physical world is, for knowledge, nothing but an instrument to explain sensations and their order, they might have expected this collapse of half their metaphysics at the approach of their positive science: for if mental existence was to be kept standing only by its supposed causal efficacy nothing could prevent the whole world from becoming presently a *bête-machine*. Psychic events have no links save through their organs and their objects; the function of the material world is, indeed, precisely to supply their linkage. The internal relations of ideas, on the other hand, are dialectical; their realm is eternal and absolutely irrelevant to the march of events. If we must speak, therefore, of causal relations between mind and body, we should say that matter is the pervasive cause of mind's distribution, and mind the pervasive cause of matter's discovery and value. To ask for an efficient cause, to trace back a force or investigate origins, is to have already turned one's face in the direction of matter and mechanical laws: no success in that undertaking can fail to be a triumph for materialism. To ask for a justification, on the other hand, is to turn no less resolutely in the direction of ideal results and actualities from which instrumentality and further use have been eliminated. Spirit is useless, being the end of things: but it is not vain, since it alone rescues all else from vanity. It is called practical when it is prophetic of its own better fulfilments, which is the case whenever forces are being turned to good uses, whenever an organism is exploring its relations and putting forth new tentacles with which to grasp the world.

We saw in the beginning that the exigences of bodily life gave consciousness its first articulation. A bodily feat, like nutrition or reproduction, is celebrated by a festival in the mind, and consciousness is a sort of ritual solemnising by prayer, jubilation, or mourning, the chief episodes in the body's fortunes. The

organs, by their structure, select the impressions possible to them from the divers influences abroad in the world, all of which, if animal organisms had learned to feed upon them, might plausibly have offered a basis for sensation. Every instinct or habitual impulse further selects from the passing bodily affections those that are pertinent to its own operation and which consequently adhere to it and modify its reactive machinery. Prevalent and notable sensations are therefore signs, presumably marking the presence of objects important for the body's welfare or for the execution of its predestined offices. So that not only are the soul's aims transcripts of the body's tendencies, but all ideas are grafted upon the interplay of these tendencies with environing forces. Early images hover about primary wants as highest conceptions do about ultimate achievements.

Thought is essentially practical in the sense that but for thought no motion would be an action, no change a progress; but thought is in no way instrumental or servile; it is an experience realised, not a force to be used. That same spontaneity in nature which has suggested a good must be trusted to fulfil it. If we look fairly at the actual resources of our minds we perceive that we are as little informed concerning the means and processes of action as concerning the reason why our motives move us. To execute the simplest intention we must rely on fate: our own acts are mysteries to us. Do I know how I open my eyes or how I walk down stairs? Is it the supervising wisdom of consciousness that guides me in these acts? Is it the mind that controls the bewildered body and points out the way to physical habits uncertain of their affinities? Or is it not much rather automatic inward machinery that executes the marvellous work, while the mind catches here and there some glimpse of the operation, now with delight and adhesion, now with impotent rebellion? When impulses work themselves out unimpeded we say we act; when they are thwarted we say we are acted upon; but in neither case do we in the least understand the natural history of what is occurring. The mind at best vaguely forecasts the result of action: a schematic verbal sense of the end to be accomplished possibly hovers in consciousness while the act is being performed; but this premonition is itself the sense of a process already present and betrays the tendency at work; it can obviously give no aid or direction to the unknown mechanical process that produced it and that must realise its own prophecy, if that prophecy is to be realised at all.

That such an unknown mechanism exists, and is adequate to explain every so-called decision, is indeed a hypothesis far outrunning detailed verification, although conceived by legitimate analogy with whatever is known about natural processes; but that the mind is not the source of itself or its own transformations is a matter of present experience; for the world is an unaccountable datum, in its existence, in its laws, and in its incidents. The highest hopes of science and morality look only to discovering those laws and bringing one set of incidents – facts of perception – into harmony with another set – facts of

preference. This hoped-for issue, if it comes, must come about in the mind; but the mind cannot be its cause since, by hypothesis, it does not possess the ideas it seeks nor has power to realise the harmonies it desiderates. These have to be waited for and begged of destiny; human will, not controlling its basis, cannot possibly control its effects. Its existence and its efforts have at best the value of a good omen. They show in what direction natural forces are moving in so far as they are embodied in given men.

Men, like all things else in the world, are products and vehicles of natural energy, and their operation counts. But their conscious will, in its moral assertiveness, is merely a sign of that energy and of that will's eventual fortunes. Dramatic terror and dramatic humour both depend on contrasting the natural pregnancy of a passion with its conscious intent. Everything in human life is ominous, even the voluntary acts. We cannot, by taking thought, add a cubit to our stature, but we may build up a world without meaning it. Man is as full of potentiality as he is of impotence. A will that represents many active forces, and is skilful in divination and augury, may long boast to be almighty without being contradicted by the event.

That thought is not self-directive appears best in the most immaterial processes. In strife against external forces men, being ignorant of their deeper selves, attribute the obvious effects of their action to their chance ideas; but when the process is wholly internal the real factors are more evenly represented in consciousness and the magical, involuntary nature of life is better perceived. My hand, guided by I know not what machinery, is at this moment adding syllable to syllable upon this paper, to the general fulfilment, perhaps, of my felt intent, yet giving that intent an articulation wholly unforeseen, and often disappointing. The thoughts to be expressed simmer half-consciously in my brain. I feel their burden and tendency without seeing their form, until the mechanical train of impulsive association, started by the perusal of what precedes or by the accidental emergence of some new idea, lights the fuse and precipitates the phrases. If this happens in the most reflective and deliberate of activities, like this of composition, how much more does it happen in positive action. "The die is cast," said Caesar, feeling a decision in himself of which he could neither count nor weigh the multitudinous causes; and so says every strong and clear intellect, every well-formed character, seizing at the same moment with comprehensive instinct both its purposes and the means by which they shall be attained. Only the fool, whose will signifies nothing, boasts to have created it himself.

We must not seek the function of thought, then, in any supposed power to discover either ends not suggested by natural impulse or means to the accomplishment of those irrational ends. Attention is utterly powerless to change or create its objects in either respect; it rather registers without surprise – for it expects nothing in particular – and watches eagerly the images bubbling up in the living mind and the processes evolving there. These processes are

themselves full of potency and promise; will and reflection are no more inconsequential than any other processes bound by natural links to the rest of the world. Even if an atomic mechanism suffices to mark the concatenation of everything in nature, including the mind, it cannot rob what it abstracts from of its natural weight and reality: a thread that may suffice to hold the pearls together is not the whole cause of the necklace. But this pregnancy and implication of thought in relation to its natural environment is purely empirical. Since natural connection is merely a principle of arrangement by which the contiguities of things may be described and inferred, there is no difficulty in admitting consciousness and all its works into the web and woof of nature. Each psychic episode would be heralded by its material antecedents; its transformations would be subject to mechanical laws, which would also preside over the further transition from thought into its material expression.

This inclusion of mind in nature, however, is as far as possible from constituting the mind's function and value, or its efficacy in a moral and rational sense. To have prepared changes in matter would give no rationality to mind unless those changes in turn paved the way to some better mental existence. The worth of natural efficacy is therefore always derivative; the utility of mind would be no more precious than the utility of matter; both borrow all their worth from the part they may play empirically in introducing those moral values which are intrinsic and self-sufficing. In so far as thought is instrumental it is not worth having, any more than matter, except for its promise; it must terminate in something truly profitable and ultimate which, being good in itself, may lend value to all that led up to it. But this ultimate good is itself consciousness, thought, rational activity; so that what instrumental mentality may have preceded might be abolished without loss, if matter suffices to sustain reason in being; or if that instrumental mentality is worth retaining, it is so only because it already contains some premonition and image of its own fulfilment. In a word, the value of thought is ideal. The material efficacy which may be attributed to it is the proper efficacy of matter – an efficacy which matter would doubtless claim if we knew enough of its secret mechanism. And when that imputed and incongruous utility was subtracted from ideas they would appear in their proper form of expressions, realisations, ultimate fruits.

The incongruity of making thought, in its moral and logical essence, an instrument in the natural world will appear from a different point of view if we shift the discussion for a moment to a transcendental level. Since the material world is an object for thought, and potential in relation to immediate experience, it can hardly lie in the same plane of reality with the thought to which it appears. The spectator on this side of the foot-lights, while surely regarded by the play as a whole, cannot expect to figure in its mechanism or to see himself strutting among the actors on the boards. He listens and is served, being at once impotent and supreme. It has been well said that

> Only the free divine the laws,
> The causeless only know the cause.

Conversely, what in such a transcendental sense is causeless and free will evidently not be causal or determinant, being something altogether universal and notional, without inherent determinations or specific affinities. The objects figuring in consciousness will have implications and will require causes; not so the consciousness itself. The Ego to which all things appear equally, whatever their form or history, is the ground of nothing incidental: no specific characters or order found in the world can be attributed to its efficacy. The march of experience is not determined by the mere fact that experience exists. Another experience, differently logical, might be equally real. Consciousness is not itself dynamic, for it has no body, no idiosyncrasy or particular locus, to be the point of origin for definite relationships. It is merely an abstract name for the actuality of its random objects. All force, implication, or direction inhere in the constitution of specific objects and live in their interplay. Logic is revealed to thought no less than nature is, and even what we call invention or fancy is generated not by thought itself but by the chance fertility of nebulous objects, floating and breeding in the primeval chaos. Where the natural order lapses, if it ever does, not mind or will or reason can possibly intervene to fill the chasm – for these are parcels and expressions of the natural order – but only nothingness and pure chance.

Thought is thus an expression of natural relations, as will is of natural affinities; yet consciousness of an object's value, while it declares the blind disposition to pursue that object, constitutes its entire worth. Apart from the pains and satisfactions involved, an impulse and its execution would be alike destitute of importance. It would matter nothing how chaotic or how orderly the world became, or what animal bodies arose or perished there; any tendencies afoot in nature, whatever they might construct or dissolve, would involve no progress or disaster, since no preferences would exist to pronounce one eventual state of things better than another. These preferences are in themselves, if the dynamic order alone be considered, works of supererogation, expressing force but not producing it, like a statue of Hercules; but the principle of such preferences, the force they express and depend upon, is some mechanical impulse itself involved in the causal process. Expression gives value to power, and the strength of Hercules would have no virtue in it had it contributed nothing to art and civilisation. That conceived basis of all life which we call matter would be a mere potentiality, an inferred instrument deprived of its function, if it did not actually issue in life and consciousness. What gives the material world a legitimate status and perpetual pertinence in human discourse is the conscious life it supports and carries in its own direction, as a ship carries its passengers or rather as a passion carries its hopes. Conscious interests first justify and moralise the mechanisms they

express. Eventual satisfactions, while their form and possibility must be determined by animal tendencies, alone render these tendencies vehicles of the good. The direction in which benefit shall lie must be determined by irrational impulse, but the attainment of benefit consists in crowning that impulse with its ideal achievement. Nature dictates what men shall seek and prompts them to seek it; a possibility of happiness is thus generated and only its fulfilment would justify nature and man in their common venture.

Satisfaction is the touchstone of value; without reference to it all talk about good and evil, progress or decay, is merely confused verbiage, pure sophistry in which the juggler adroitly withdraws attention from what works the wonder – namely, that human and moral colouring to which the terms he plays with owe whatever efficacy they have. Metaphysicians sometimes so define the good as to make it a matter of no importance; not seldom they give that name to the sum of all evils. A good, absolute in the sense of being divorced from all natural demand and all possible satisfaction, would be as remote as possible from goodness: to call it good is mere disloyalty to morals, brought about by some fantastic or dialectical passion. In excellence there is an essential bias, an opposition to the possible opposite; this bias expresses a mechanical impulse, a situation that has stirred the senses and the will. Impulse makes value possible; and the value becomes actual when the impulse issues in processes that give it satisfaction and have a conscious worth. Character is the basis of happiness and happiness the sanction of character.[1]

That thought is nature's concomitant expression or entelechy, never one of her instruments, is a truth long ago divined by the more judicious thinkers, like Aristotle and Spinoza; but it has not met with general acceptance or even consideration. It is obstructed by superficial empiricism, which associates the better-known aspects of events directly together, without considering what mechanical bonds may secretly unite them; it is obstructed also by the traditional mythical idealism, intent as this philosophy is on proving nature to be the expression of something ulterior and non-natural and on hugging the fatal misconception that ideals and eventual goods are creative and miraculous forces, without perceiving that it thereby renders goods and ideals perfectly senseless; for how can anything be a good at all to which some existing nature is not already directed? It may therefore be worth while, before leaving this

[1] Aristippus asked Socrates "whether he knew anything good, so that if he answered by naming food or drink or money or health or strength or valour or anything of that sort, he might at once show that it was sometimes an evil. Socrates, however, knew very well that if anything troubles us what we demand is its cure, and he replied in the most pertinent fashion. 'Are you asking me,' he said, 'if I know anything good for a fever?' 'Oh, no,' said the other. 'Or for sore eyes?' 'Not that, either.' 'Or for hunger?' 'No, not for hunger.' 'Well, then,' said he, 'if you ask me whether I know a good that is good for nothing, I neither know it nor want to know it.'" – Xenophon, Memorabilia, iii., 8.

phase of the subject, to consider one or two prejudices which might make it sound paradoxical to say, as we propose, that ideals are ideal and nature natural.

Of all forms of consciousness the one apparently most useful is pain, which is also the one most immersed in matter and most opposite to ideality and excellence. Its utility lies in the warning it gives: in trying to escape pain we escape destruction. That we desire to escape pain is certain; its very definition can hardly go beyond the statement that pain is that element of feeling which we seek to abolish on account of its intrinsic quality. That this desire, however, should know how to initiate remedial action is a notion contrary to experience and in itself unthinkable. If pain could have cured us we should long ago have been saved. The bitterest quintessence of pain is its helplessness, and our incapacity to abolish it. The most intolerable torments are those we feel gaining upon us, intensifying and prolonging themselves indefinitely. This baffling quality, so conspicuous in extreme agony, is present in all pain and is perhaps its essence. If we sought to describe by a circumlocution what is of course a primary sensation, we might scarcely do better than to say that pain is consciousness at once intense and empty, fixing attention on what contains no character, and arrests all satisfactions without offering anything in exchange. The horror of pain lies in its intolerable intensity and its intolerable tedium. It can accordingly be cured either by sleep or by entertainment. In itself it has no resource; its violence is quite helpless and its vacancy offers no expedients by which it might be unknotted and relieved.

Pain is not only impotent in itself but is a sign of impotence in the sufferer. Its appearance, far from constituting its own remedy, is like all other organic phenomena subject to the law of inertia and tends only to its own continuance. A man's hatred of his own condition no more helps to improve it than hatred of other people tends to improve them. If we allowed ourselves to speak in such a case of efficacy at all, we should say that pain perpetuates and propagates itself in various ways, now by weakening the system, now by prompting convulsive efforts, now by spreading to other beings through the contagion of sympathy or vengeance. In fact, however, it merely betrays a maladjustment which has more or less natural stability. It may be instantaneous only; by its lack of equilibrium it may involve the immediate destruction of one of its factors. In that case we fabulously say that the pain has instinctively removed its own cause. Pain is here apparently useful because it expresses an incipient tension which the self-preserving forces in the organism are sufficient to remove. Pain's appearance is then the sign for its instant disappearance; not indeed by virtue of its inner nature or of any art it can initiate, but merely by virtue of mechanical associations between its cause and its remedy. The burned child dreads the fire and, reading only the surface of his life, fancies that the pain once felt and still remembered is the ground of his new prudence. Punishments, however, are not always efficacious, as everyone

knows who has tried to govern children or cities by the rod; suffering does not bring wisdom nor even memory, unless intelligence and docility are already there; that is, unless the friction which the pain betrayed sufficed to obliterate permanently one of the impulses in conflict. This readjustment, on which real improvement hangs and which alone makes "experience" useful, does not correspond to the intensity or repetition of the pains endured; it corresponds rather to such a plasticity in the organism that the painful conflict is no longer produced.

Threatened destruction would not involve pain unless that threatened destruction were being resisted; so that the reaction which pain is supposed to cause must already be taking place before pain can be felt. A will without direction cannot be thwarted; so that inhibition cannot be the primary source of any effort or of any ideal. Determinate impulses must exist already for their inhibition to have taken place or for the pain to arise which is the sign of that inhibition. The child's dread of the fire marks the acceleration of that impulse which, when he was burned, originally enabled him to withdraw his hand; and if he did not now shrink in anticipation he would not remember the pain nor know to what to attach his terror. Sight now suffices to awaken the reaction which touch at first was needed to produce; the will has extended its line of battle and thrown out its scouts farther afield; and pain has been driven back to the frontiers of the spirit. The conflicting reactions are now peripheral and feeble; the pain involved in aversion is nothing to that once involved in the burn. Had this aversion to fire been innate, as many aversions are, no pain would have been caused, because no profound maladjustment would have occurred. The surviving attraction, checked by fear, is a remnant of the old disorganisation in the brain which was the seat of conflicting reactions.

To say that this conflict is the guide to its own issue is to talk without thinking. The conflict is the sign of inadequate organisation, or of non-adaptation in the given organism to the various stimuli which irritate it. The reconstruction which follows this conflict, when it indeed follows, is of course a new and better adaptation; so that what involves the pain may often be a process of training which directs reaction into new and smoother channels. But the pain is present whether a permanent adaptation is being attained or not. It is present in progressive dissolution and in hopeless and exhausting struggles far more than in education or in profitable correction. Toothache and sea-sickness, birth-pangs and melancholia are not useful ills. The intenser the pain the more probable its uselessness. Only in vanishing is it a sign of progress; in occurring it is an omen of defeat, just as disease is an omen of death, although, for those diseased already, medicine and convalescence may be approaches to health again. Where a man's nature is out of gear and his instincts are inordinate, suffering may be a sign that a dangerous peace, in which impulse was carrying him ignorantly into paths without

issue, is giving place to a peace with security in which his reconstructed character may respond without friction to the world, and enable him to gather a clearer experience and enjoy a purer vitality. The utility of pain is thus apparent only, and due to empirical haste in collating events that have no regular nor inward relation; and even this imputed utility pain has only in proportion to the worthlessness of those who need it.

A second current prejudice which may deserve notice suggests that an organ, when its function is perfect, becomes unconscious, so that if adaptation were complete life would disappear. The well-learned routine of any mechanical art passes into habit, and habit into unconscious operation. The virtuoso is not aware how he manipulates his instrument; what was conscious labour in the beginning has become instinct and miracle in the end. Thus it might appear that to eliminate friction and difficulty would be to eliminate consciousness, and therefore value, from the world. Life would thus be involved in a contradiction and moral effort in an absurdity; for while the constant aim of practice is perfection and that of labour ease, and both are without meaning or standard unless directed to the attainment of these ends, yet such attainment, if it were actual, would be worthless, so that what alone justifies effort would lack justification and would in fact be incapable of existence. The good musician must strive to play perfectly, but, alas, we are told, if he succeeded he would have become an automaton. The good man must aspire to holiness, but, alas, if he reached holiness his moral life would have evaporated.

These melodramatic prophecies, however, need not alarm us. They are founded on nothing but rhetoric and small allegiance to any genuine good. When we attain perfection of function we lose consciousness of the medium, to become more clearly conscious of the result. The eye that does its duty gives no report of itself and has no sense of muscular tension or weariness; but it gives all the brighter and steadier image of the object seen. Consciousness is not lost when focussed, and the labour of vision is abolished in its fruition. So the musician, could he play so divinely as to be unconscious of his body, his instrument, and the very lapse of time, would be only the more absorbed in the harmony, more completely master of its unities and beauty. At such moments the body's long labour at last brings forth the soul. Life from its inception is simply some partial natural harmony raising its voice and bearing witness to its own existence; to perfect that harmony is to round out and intensify that life. This is the very secret of power, of joy, of intelligence. Not to have understood it is to have passed through life without understanding anything.

The analogy extends to morals, where also the means may be advantageously forgotten when the end has been secured. That leisure to which work is directed and that perfection in which virtue would be fulfilled are so far from being apathetic that they are states of pure activity, by containing

which other acts are rescued from utter passivity and unconsciousness. Impure feeling ranges between two extremes: absolute want and complete satisfaction. The former limit is reached in anguish, madness, or the agony of death, when the accidental flux of things in contradiction has reached its maximum or vanishing point, so that the contradiction and the flux themselves disappear by diremption. Such feeling denotes inward disorganisation and a hopeless conflict of reflex actions tending toward dissolution. The second limit is reached in contemplation, when anything is loved, understood, or enjoyed. Synthetic power is then at its height; the mind can survey its experience and correlate all the motions it suggests. Power in the mind is exactly proportionate to representative scope, and representative scope to rational activity. A steady vision of all things in their true order and worth results from perfection of function and is its index; it secures the greatest distinctness in thought together with the greatest decision, wisdom, and ease in action, as the lightning is brilliant and quick. It also secures, so far as human energies avail, its own perpetuity, since what is perfectly adjusted within and without lasts long and goes far.

To confuse means with ends and mistake disorder for vitality is not unnatural to minds that hear the hum of mighty workings but can imagine neither the cause nor the fruits of that portentous commotion. All functions, in such chaotic lives, seem instrumental functions. It is then supposed that what serves no further purpose can have no value, and that he who suffers no offuscation can have no feeling and no life. To attain an ideal seems to destroy its worth. Moral life, at that low level, is a fantastic game only, not having come in sight of humane and liberal interests. The barbarian's intensity is without seriousness and his passion without joy. His philosophy, which means to glorify all experience and to digest all vice, is in truth an expression of pathetic innocence. It betrays a rudimentary impulse to follow every beckoning hand, to assume that no adventure and no bewitchment can be anything but glorious. Such an attitude is intelligible in one who has never seen anything worth seeing nor loved anything worth loving. Immaturity could go no farther than to acknowledge no limits defining will and happiness. When such limits, however, are gradually discovered and an authoritative ideal is born of the marriage of human nature with experience, happiness becomes at once definite and attainable; for adjustment is possible to a world that has a fruitful and intelligible structure.

Such incoherences, which might well arise in ages without traditions, may be preserved and fostered by superstition. Perpetual servile employments and subjection to an irrational society may render people incapable even of conceiving a liberal life. They may come to think their happiness no longer separable from their misery and to fear the large emptiness, as they deem it, of a happy world. Like the prisoner of Chillon, after so long a captivity, they would regain their freedom with a sigh. The wholesome influences of nature,

however, would soon revive their wills, contorted by unnatural oppression, and a vision of perfection would arise within them upon breathing a purer air. Freedom and perfection are synonymous with life. The peace they bring is one

> whose names are also rapture, power,
> Clear sight, and love; for these are parts of peace.

Thought belongs to the sphere of ultimate results. What, indeed, could be more fitting than that consciousness, which is self-revealing and transcendentally primary, should be its own excuse for being and should contain its own total value, together with the total value of everything else? What could be more proper than that the whole worth of ideas should be ideal? To make an idea instrumental would be to prostitute what, being self-existent, should be self-justifying. That continual absoluteness which consciousness possesses, since in it alone all heaven and earth are at any moment revealed, ought to convince any radical and heart-searching philosopher that all values should be continually integrated and realised there, where all energies are being momently focussed. Thought is a fulfilment; its function is to lend utility to its causes and to make actual those conceived and subterranean processes which find in it their ultimate expression. Thought is nature represented; it is potential energy producing life and becoming an actual appearance.

The conditions of consciousness, however, are far from being its only theme. As consciousness bears a transcendent relation to the dynamic world (for it is actual and spiritual, while the dynamic is potential and material) so it may be exuberant and irresponsibly rich. Although its elements, in point of distribution and derivation, are grounded in matter, as music is in vibrations, yet in point of character the result may be infinitely redundant. The complete musician would devote but a small part of his attention to the basis of music, its mechanism, psychology, or history. Long before he had represented to his mind the causes of his art, he would have proceeded to practise and enjoy it. So sense and imagination, passion and reason, may enrich the soil that breeds them and cover it with a maze of flowers.

The theme of consciousness is accordingly far more than the material world which constitutes its basis, though this also is one of its themes; thought is no less at home in various expressions and embroideries with which the material world can be overlaid in imagination. The material world is conceived by digging beneath experience to find its cause; it is the efficacious structure and skeleton of things. This is the subject of scientific retrospect and calculation. The forces disclosed by physical studies are of course not directed to producing a mind that might merely describe them. A force is expressed in many other ways than by being defined; it may be felt, resisted, embodied, transformed, or symbolised. Forces work; they are not, like mathematical

concepts, exhausted in description. From that matter which might be describable in mechanical formulae there issue notwithstanding all manner of forms and harmonies, visible, audible, imaginable, and passionately prized. Every phase of the ideal world emanates from the natural and loudly proclaims its origin by the interest it takes in natural existences, of which it gives a rational interpretation. Sense, art, religion, society, express nature exuberantly and in symbols long before science is added to represent, by a different abstraction, the mechanism which nature contains.

HOW RELIGION MAY BE AN EMBODIMENT OF REASON

George Santayana. "How Religion May Be an Embodiment of Reason." *The Life of Reason*, vol. 3: *Reason in Religion* (New York: Charles Scribner's Sons, 1905), chap. 1, pp. 3–14.

Experience has repeatedly confirmed that well-known maxim of Bacon's, that "a little philosophy inclineth man's mind to atheism, but depth in philosophy bringeth men's minds about to religion." In every age the most comprehensive thinkers have found in the religion of their time and country something they could accept, interpreting and illustrating that religion so as to give it depth and universal application. Even the heretics and atheists, if they have had profundity, turn out after a while to be forerunners of some new orthodoxy. What they rebel against is a religion alien to their nature; they are atheists only by accident, and relatively to a convention which inwardly offends them, but they yearn mightily in their own souls after the religious acceptance of a world interpreted in their own fashion. So it appears in the end that their atheism and loud protestation were in fact the hastier part of their thought, since what emboldened them to deny the poor world's faith was that they were too impatient to understand it. Indeed, the enlightenment common to young wits and worm-eaten old satirists, who plume themselves on detecting the scientific ineptitude of religion – something which the blindest half see – is not nearly enlightened enough: it points to notorious facts incompatible with religious tenets literally taken, but it leaves unexplored the habits of thought from which those tenets sprang, their original meaning, and their true function. Such studies would bring the sceptic face to face with the mystery and pathos of mortal existence. They would make him understand why religion is so profoundly moving and in a sense so profoundly just. There must needs be something humane and necessary in an influence that has become the most general sanction of virtue, the chief occasion for; art and philosophy, and the source, perhaps, of the best human happiness. If nothing, as Hooker said, is "so malapert as a splenetic religion," a sour irreligion is almost as perverse.

At the same time, when Bacon penned the sage epigram we have quoted he forgot to add that the God to whom depth in philosophy brings back men's minds is far from being the same from whom a little philosophy estranges

them. It would be pitiful indeed if mature reflection bred no better conceptions than those which have drifted down the muddy stream of time, where tradition and passion have jumbled everything together. Traditional conceptions, when they are felicitous, may be adopted by the poet, but they must be purified by the moralist and disintegrated by the philosopher. Each religion, so dear to those whose life it sanctifies, and fulfilling so necessary a function in the society that has adopted it, necessarily contradicts every other religion, and probably contradicts itself. What religion a man shall have is a historical accident, quite as much as what language he shall speak. In the rare circumstances where a choice is possible, he may, with some difficulty, make an exchange; but even then he is only adopting a new convention which may be more agreeable to his personal temper but which is essentially as arbitrary as the old.

The attempt to speak without speaking any particular language is not more hopeless than the attempt to have a religion that shall be no religion in particular. A courier's or a dragoman's speech may indeed be often unusual and drawn from disparate sources, not without some mixture of personal originality; but that private jargon will have a meaning only because of its analogy to one or more conventional languages and its obvious derivation from them. So travellers from one religion to another, people who have lost their spiritual nationality, may often retain a neutral and confused residuum of belief, which they may egregiously regard as the essence of all religion, so little may they remember the graciousness and naturalness of that ancestral accent which a perfect religion should have. Yet a moment's probing of the conceptions surviving in such minds will show them to be nothing but vestiges of old beliefs, creases which thought, even if emptied of all dogmatic tenets, has not been able to smooth away at its first unfolding. Later generations, if they have any religion at all, will be found either to revert to ancient authority, or to attach themselves spontaneously to something wholly novel and immensely positive, to some faith promulgated by a fresh genius and passionately embraced by a converted people. Thus every living and healthy religion has a marked idiosyncrasy. Its power consists in its special and surprising message and in the bias which that revelation gives to life. The vistas it opens and the mysteries propounds are another world to live in; and another world to live in – whether we expect ever to pass wholly into it or no – is what we mean by having a religion.

What relation, then, does this great business of the soul, which we call religion, bear to the Life of Reason? That the relation between the two is close seems clear from several circumstances. The Life of Reason is the seat of all ultimate values. Now the history of mankind will show us that whenever spirits at once lofty and intense have seemed to attain the highest joys, they have envisaged and attained them in religion. Religion would therefore seem to be a vehicle or a factor in rational life, since the ends of rational life are

attained by it. Moreover, the Life of Reason is an ideal to which everything in the world should be subordinated; it establishes lines of moral cleavage everywhere and makes right eternally different from wrong. Religion does the same thing. It makes absolute moral decisions. It sanctions, unifies, and transforms ethics. Religion thus exercises a function of the Life of Reason. And a further function which is common to both is that of emancipating man from his personal limitations. In different ways religions promise to transfer the soul to better conditions. A supernaturally favoured kingdom is to be established for posterity upon earth, or for all the faithful in heaven, or the soul is to be freed by repeated purgations from all taint and sorrow, or it is to be lost in the absolute, or it is to become an influence and an object of adoration in the places it once haunted or wherever the activities it once loved may be carried on by future generations of its kindred. Now reason in its way lays before us all these possibilities: it points to common objects, political and intellectual, in which an individual may lose what is mortal and accidental in himself and immortalise what is rational and human; it teaches us how sweet and fortunate death may be to those whose spirit can still live in their country and in their ideas; it reveals the radiating effects of action and the eternal objects of thought.

Yet the difference in tone and language must strike us, so soon as it is philosophy that speaks. That change should remind us that even if the function of religion and that of reason coincide, this function is performed in the two cases by very different organs. Religions are many, reason one. Religion consists of conscious ideas, hopes, enthusiasms, and objects of worship; it operates by grace and flourished by prayer. Reason, on the other hand, is a mere principle or potential order, on which, indeed, we may come to reflect, but which exists in us ideally only, without variation or stress of any kind. We conform or do not conform to it; it does not urge or chide us, nor call for any emotions on our part other than those naturally aroused by the various objects which it unfolds in their true nature and proportion. Religion brings some order into life by weighting it with new materials. Reason adds to the natural materials only the perfect order which it introduces into them. Rationality is nothing but a form, an ideal constitution which experience may more or less embody. Religion is a part of experience itself, a mass of sentiments and ideas. The one is an inviolate principle, the other a changing and struggling force. And yet this struggling and changing force of religion, seems to direct man toward something eternal. It seems to make for an ultimate harmony within the soul and for an ultimate harmony between the soul and all the soul depends upon. So that religion, in its intent, is a more conscious and direct pursuit of the Life of Reason than is society, science, or art. For these approach and fill out the ideal life tentatively and piecemeal, hardly regarding the goal or caring for the ultimate justification of their instinctive aims. Religion also has an instinctive and blind side, and bubbles

up in all manner of chance practices and intuitions; soon, however, it feels its way toward the heart of things, and, from whatever quarter it may come, veers in the direction of the ultimate.

Nevertheless, we must confess that this religious pursuit of the Life of Reason has been singularly abortive. Those within the pale of each religion may prevail upon themselves to express satisfaction with its results, thanks to a fond partiality in reading the past and generous draughts of hope for the future; but any one regarding the various religions at once and comparing their achievements with what reason requires, must feel how terrible is the disappointment which they have one and all prepared for mankind. Their chief anxiety has been to offer imaginary remedies for mortal ills, some of which are incurable essentially, while others might have been really cured by well-directed effort. The Greek oracles, for instance, pretended to heal our natural ignorance, which has its appropriate though difficult cure, while the Christian vision of heaven pretended to be an antidote to our natural death, the inevitable correlate of birth and of a changing and conditioned existence. By methods of this sort little can be done for the real betterment of life. To confuse intelligence and dislocate sentiment by gratuitous fictions is a short-sighted way of pursuing happiness. Nature is soon avenged. An unhealthy exaltation and a one-sided morality have to be followed by regrettable reactions. When these come, the real rewards of life may seem vain to a relaxed vitality, and the very name of virtue may irritate young spirits untrained in any natural excellence. Thus religion too often debauches the morality it comes to sanction, and impedes the science it ought to fulfil.

What is the secret of this ineptitude? Why does religion, so near to rationality in its purpose, fall so far short of it in its texture and in its results? The answer is easy: Religion pursues rationality through the imagination. When it explains events or assigns causes, it gives imaginative substitute for science. When it gives precepts, insinuates ideals, or remoulds aspiration, it is an imaginative substitute for wisdom – I mean for the deliberate and impartial pursuit of all good. The conditions and the aims of life are both represented in religion poetically, but this poetry tends to arrogate to itself literal truth and moral authority, neither of which it possesses. Hence the depth and importance of religion become intelligible no less than its contradictions and practical disasters. Its object is the same as that of reason, but its method is to proceed by intuition and by unchecked poetical conceits. These are repeated and vulgarised in proportion to their original fineness and significance, till they pass for reports of objective truth and come to constitute a world of faith, superposed upon the world of experience and regarded as materially enveloping it, if not in space at least in time and in existence. The only truth of religion comes from its interpretation of life, from its symbolic rendering of that moral experience which it springs out of and which it seeks to elucidate. Its falsehood comes from the insidious misunderstanding which

clings to it, to the effect that these poetic conceptions are not merely representations of experience as it is or should be, but are rather information about experience or reality elsewhere – an experience and reality which, strangely enough, supply just the defects betrayed by reality and experience here.

Thus religion has the same original relation to life that poetry has; only poetry, which never pretends to literal validity, adds a pure value to existence, the value of a liberal imaginative exercise. The poetic value of religion would initially be greater than that of poetry itself, because religion deals with higher and more practical themes, with sides of life which are in greater need of some imaginative touch and ideal interpretation than are those pleasant or pompous things which ordinary poetry dwells upon. But this initial advantage is neutralised in part by the abuse to which religion is subject, whenever its symbolic rightness is taken for scientific truth. Like poetry, it improves the world only by imagining it improved, but not content with making this addition to the mind's furniture – an addition which might be useful and ennobling – it thinks to confer a more radical benefit by persuading mankind that, in spite of appearances, the world is really such as that rather arbitrary idealisation has painted it. This spurious satisfaction is naturally the prelude to many a disappointment, and the soul has infinite trouble to emerge again from the artificial problems and sentiments into which it is thus plunged. The value of religion becomes equivocal. Religion remains an imaginative achievement, a symbolic representation of moral reality which may have a most important function in vitalising the mind and in transmitting, by way of parables, the lessons of experience. But it becomes at the same time a continuous incidental deception; and this deception, in proportion as it is strenuously denied to be such, can work indefinite harm in the world and in the conscience.

On the whole, however, religion should not be conceived as having taken the place of anything better, but rather as having come to relieve situations which, but for its presence, would have been infinitely worse. In the thick of active life, or in the monotony of practical slavery, there is more need to stimulate fancy than to control it. Natural instinct is not much disturbed in the human brain by what may happen in that thin superstratum of ideas which commonly overlays it. We must not blame religion for preventing the development of a moral and natural science which at any rate would seldom have appeared; we must rather thank it for the sensibility, the reverence, the speculative insight which it has introduced into the world.

We may therefore proceed to analyse the significance and the function which religion has had at its different stages, and, without disguising or in the least condoning its confusion with literal truth, we may allow ourselves to enter as sympathetically as possible into its various conceptions and emotions. They have made up the inner life of many sages, and of all those who without great genius or learning have lived steadfastly in the spirit. The feeling of

reverence should itself be treated with reverence, although not at a sacrifice of truth, with which alone, in the end, reverence is compatible. Nor have we any reason to be intolerant of the partialities and contradictions which religions display. Were we dealing with a science, such contradictions would have to be instantly solved and removed; but when we are concerned with the poetic interpretation of experience, contradiction means only variety, and variety means spontaneity, wealth of resource, and a nearer approach to total adequacy.

If we hope to gain any understanding of these matters we must begin by taking them out of that heated and fanatical atmosphere in which the Hebrew tradition has enveloped them. The Jews had no philosophy, and when their national traditions came to be theoretically explicated and justified, they were made to issue in a puerile scholasticism and a rabid intolerance. The question of monotheism, for instance, was a terrible question to the Jews. Idolatry did not consist in worshipping a god who, not being ideal, might be unworthy of worship, but rather in recognising other gods than the one worshipped in Jerusalem. To the Greeks, on the contrary, whose philosophy was enlightened and ingenuous, monotheism and polytheism seemed perfectly innocent and compatible. To say God or the gods was only to use different expressions for the same influence, now viewed in its abstract unity and correlation with all existence, now viewed in its various manifestations in moral life, in nature, or in history. So that what in Plato, Aristotle, and the Stoics meets us at every step – the combination of monotheism with polytheism – is no contradiction, but merely an intelligent variation of phrase to indicate various aspects or functions in physical and moral things. When religion appears to us in this light its contradictions and controversies lose all their bitterness. Each doctrine will simply represent the moral plane on which they live who have devised or adopted it. Religions will thus be better or worse, never true or false. We shall be able to lend ourselves to each in turn, and seek to draw from it the secret of its inspiration.

PSYCHOLOGY

George Santayana. "Psychology." *The Life of Reason*, vol. 5: *Reason in Science* (New York: Charles Scribner's Sons, 1906), chap. 5, pp. 126–166.

If psychology is a science, many things that books of psychology contain should be excluded from it. One is social imagination. Nature, besides having a mechanical form and wearing a garment of sensible qualities, makes a certain inner music in the beholder's mind, inciting him to enter into other bodies and to fancy the new and profound life which he might lead there. Who, as he watched a cat basking in the sun, has not passed into that vigilant eye and felt all the leaps potential in that luxurious torpor? Who has not attributed some little romance to the passer-by? Who has not sometimes exchanged places even with things inanimate, and drawn some new moral experience from following the movement of stars or of daffodils? All this is idle musing or at best poetry; yet our ordinary knowledge of what goes on in men's minds is made of no other stuff. True, we have our own mind to go by, which presumably might be a fair sample of what men's minds are; but unfortunately our notion of ourselves is of all notions the most biassed and idealistic. If we attributed to other men only such obvious reasoning, sound judgment, just preferences, honest passions, and blameless errors as we discover in ourselves, we should take but an insipid and impractical view of mankind.

In fact, we do far better: for what we impute to our fellow-men is suggested by their conduct or by an instant imitation of their gesture and expression. These manifestations, striking us in all their novelty and alien habit, and affecting our interests in all manner of awkward ways, create a notion of our friends' natures which is extremely vivid and seldom extremely flattering.

Such romancing has the cogency proper to dramatic poetry; it is persuasive only over the third person, who has never had, but has always been about to have, the experience in question. Drawn from the potential in one's self, it describes at best the possible in others. The thoughts of men are incredibly evanescent, merely the foam of their labouring natures; and they doubtless vary much more than our trite classifications allow for. This is what makes passions and fashions, religions and philosophies, so hard to conceive when once the trick of them is a little antiquated. Languages are hardly more foreign to one another than are the thoughts uttered in them. We should give men credit for originality at least in their dreams, even if they have little of it

to show elsewhere; and as it was discovered but recently that all memories are not furnished with the like material images, but often have no material images whatever, so it may have to be acknowledged that the disparity in men's soliloquies is enormous, and that some races, perhaps, live content without soliloquising at all.

Nevertheless, in describing what happens, or in enforcing a given view of things, we constantly refer to universal experience as if everybody was agreed about what universal experience is and had personally gathered it all since the days of Adam. In fact, each man has only his own, the remnant saved from his personal acquisitions. On the basis of this his residual endowment, he has to conceive all nature, with whatever experiences may have fallen there to the lot of others. Universal experience is a comfortable fiction, a distinctly ideal construction, and no fund available for any one to draw from; which of course is not to deny that tradition and books, in transmitting materially the work of other generations, tend to assimilate us also to their mind. The result of their labours, in language, learning, and institutions, forms a hothouse in which to force our seedling fancy to a rational growth; but the influence is physical, the environment is material, and its ideal background or significance has to be inferred by us anew, according to our imaginative faculty and habits. Past experience, apart from its monuments, is fled for ever out of mortal reach. It is now a parcel of the motionless ether, of the ineffectual truth about what once was. To know it we must evoke it within ourselves, starting from its inadequate expressions still extant in the world. This reconstruction is highly speculative and, as Spinoza noted, better evidence of what we are than of what other men have been.

When we appeal to general experience, then, what we really have to deal with is our interlocutor's power of imagining that experience; for the real experience is dead and ascended into heaven, where it can neither answer nor hear. Our agreements or divergences in this region do not touch science; they concern only friendship and unanimity. All our proofs are, as they say in Spain, pure conversation; and as the purpose and best result can be only to kindle intelligence and propagate an ideal art, the method should be Socratic, genial, literary. In these matters, the alternative to imagination is not science but sophistry. We may perhaps entangle our friends in their own words, and force them for the moment to say what they do not mean, and what it is not in their natures to think; but the bent bow will spring back, perhaps somewhat sharply, and we shall get little thanks for our labour. There would be more profit in taking one another frankly by the hand and walking together along the outskirts of real knowledge, pointing to the material facts which we all can see, nature, the monuments, the texts, the actual ways and institutions of men; and in the presence of such a stimulus, with the contagion of a common interest, the plastic mind would respond of itself to the situation, and we should be helping one another to understand whatever lies within the range

of our fancy, be it in antiquity or in the human heart. That would be a true education; and while the result could not possibly be a science, not even a science of people's states of mind, it would be a deepening of humanity in ourselves and a wholesome knowledge of our ignorance.

In what is called psychology this loose, imaginative method is often pursued, although the field covered may be far narrower. Any generic experience of which a writer pretends to give an exact account must be reconstructed *ad hoc*; it is not the experience that necessitates the description, but the description that recalls the experience, defining it in a novel way. When La Rochefoucauld says, for instance, that there is something about our friend's troubles that secretly pleases us, many circumstances in our own lives, or in other people's, may suddenly recur to us to illustrate that *aperçu*; and we may be tempted to say, There is a truth. But is it a scientific truth? Or is it merely a bit of satire, a ray from a literary flashlight, giving a partial clearness for a moment to certain jumbled memories? If the next day we open a volume of Adam Smith, and read that man is naturally benevolent, that he cannot but enact and share the vicissitudes of his fellow-creatures, and that another man's imminent danger or visible torment will cause in him a distress little inferior to that felt by the unfortunate sufferer, we shall probably think this a truth also, and a more normal and a profounder truth than the other. But is it a law? Is it a scientific discovery that can lead us to definite inferences about what will happen or help us to decompose a single event, accurately and without ambiguity, into its component forces? Not only is such a thing impossible, but the Scotch philosopher's amiable generalities, perhaps largely applicable to himself and to his friends of the eighteenth century, may fail altogether to fit an earlier or a later age; and every new shade of brute born into the world will ground a new "theory of the moral sentiments."

The whole cogency of such psychology, therefore, lies in the ease with which the hearer, on listening to the analysis, recasts something in his own past after that fashion. These endless rival apperceptions regard facts that, until they are referred to their mechanical ground, show no continuity and no precision in their march. The apperception of them, consequently, must be doubly arbitrary and unstable, for there is no method in the subject-matter and there is less in the treatment of it. The views, however, are far from equal in value. Some may be more natural, eloquent, enlightening, than others; they may serve better the essential purpose of reflection, which is to pick out and bring forward continually out of the past what can have a value for the present. The spiritual life in which this value lies is practical in its associations, because it understands and dominates what touches action; yet it is contemplative in essence, since successful action consists in knowing what you are attempting and in attempting what you can find yourself achieving. Plan and performance will alike appeal to imagination and be appreciated through it; so that what trains imagination refines the very stuff that life is made of.

Science is instrumental in comparison, since the chief advantage that comes of knowing accurately is to be able, with safety, to imagine freely. But when it is science and accurate knowledge that we pursue, we should not be satisfied with literature.

When discourse on any subject would be persuasive, it appeals to the interlocutor to think in a certain dynamic fashion, inciting him, not without leading questions, to give shape to his own sentiments. Knowledge of the soul, insight into human nature and experience, are no doubt requisite in such an exercise; yet this insight is in these cases a vehicle only, an instinctive method, while the result aimed at is agreement on some further matter, conviction and enthusiasm, rather than psychological information. Thus if I declare that the storms of winter are not so unkind as benefits forgot, I say something which if true has a certain psychological value, for it could be inferred from that assertion that resentment is generally not proportionate to the injury received but rather to the surprise caused, so that it springs from our own foolishness more than from other people's bad conduct. Yet my observation was not made in the interest of any such inferences: it was made to express an emotion of my own, in hopes of kindling in others a similar emotion. It was a judgment which others were invited to share. There was as little exact science about it as if I had turned it into frank poetry and exclaimed, "Blow, blow, thou winter's wind!" Knowledge of human nature might be drawn even from that apostrophe, and a very fine shade of human feeling is surely expressed in it, as Shakespeare utters it; but to pray or to converse is not for that reason the same thing as to pursue science.

Now it constantly happens in philosophic writing that what is supposed to go on in the human mind is described and appealed to in order to support some observation or illustrate some argument – as continually, for instance, in the older English critics of human nature, or in these very pages. What is offered in such cases is merely an invitation to think after a certain fashion. A way of grasping or interpreting some fact is suggested, with a more or less civil challenge to the reader to resist the suasion of his own experience so evoked and represented. Such a method of appeal may be called psychological, in the sense that it relies for success on the total movement of the reader's life and mind, without forcing a detailed assent through ocular demonstration or pure dialectic; but the psychology of it is a method and a resource rather than a doctrine. The only doctrine aimed at in such philosophy is a general reasonableness, a habit of thinking straight from the elements of experience to its ultimate and stable deliverance. This is what in his way a poet or a novelist would do. Fiction swarms with such sketches of human nature and such renderings of the human mind as a critical philosopher depends upon for his construction. He need not be interested in the pathology of individuals nor even in the natural history of man; his effort is wholly directed toward improving the mind's economy and infusing reason into it as one might

religion, not without diligent self-examination and a public confession of sin. The human mind is nobody's mind in particular, and the science of it is necessarily imaginative. No one can pretend in philosophic discussion any more than in poetry that the experience described is more than typical. It is given out not for a literal fact, existing in particular moments or persons, but for an imaginative expression of what nature and life have impressed on the speaker. In so far as others live in the same world they may recognise the experience so expressed by him and adopt his interpretation; but the aptness of his descriptions and analyses will not constitute a science of mental states, but rather – what is a far greater thing – the art of stimulating and consolidating reflection in general.

There is a second constituent of current psychology which is indeed a science, but not a science of matters of fact – I mean the dialectic of ideas. The character of father, for example, implies a son, and this relation, involved in the ideas both of son and of father, implies further that a transmitted essence or human nature is shared by both. Every idea, if its logical texture is reflected upon, will open out into a curious world constituted by distinguishing the constituents of that idea more clearly and making explicit its implicit structure and relations. When an idea has practical intent and is a desire, its dialectic is even more remarkable. If I love a man I thereby love all those who share whatever makes me love him, and I thereby hate whatever tends to deprive him of this excellence. If it should happen, however, that those who resembled him most in amiability – say by flattering me no less than he did – were precisely his mortal enemies, the logic of my affections would become somewhat involved. I might end either by striving to reconcile the rivals or by discovering that what I loved was not the man at all, but only an office exercised by him in my regard which any one else might also exercise.

These inner lucubrations, however, while they lengthen the moment's vista and deepen present intent, give no indication whatever about the order or distribution of actual feelings. They are out of place in a psychology that means to be an account of what happens in the world. For these dialectical implications do not actually work themselves out. They have no historical or dynamic value. The man that by mistake or courtesy I call a father may really have no son, any more than Herodotus for being the father of history; or having had a son, he may have lost him; or the creature sprung from his loins may be a misshapen idiot, having nothing ideal in common with his parent. Similarly my affection for a friend, having causes much deeper than discourse, may cling to him through all transformations in his qualities and in his attitude toward me; and it may never pass to others for resembling him, nor take, in all its days, a Platonic direction. The impulse on which that dialectic was based may exhaust its physical energy, and all its implications may be nipped in the bud and be condemned for ever to the limbo of things unborn.

Spinoza's account of the passions is a beautiful example of dialectical psychology, beautiful because it shows so clearly the possibilities and impossibilities in such a method. Spinoza began with self-preservation, which was to be the principle of life and the root of all feelings. The violence done to physics appears in this beginning. Self-preservation, taken strictly, is a principle not illustrated in nature, where everything is in flux, and where habits destructive or dangerous to the body are as conspicuous as protective instincts. Physical mechanism requires reproduction, which implies death, and it admits suicide. Spinoza himself, far too noble a mind to be fixed solely on preserving its own existence, was compelled to give self-preservation an extravagant meaning in order to identify it with "intellectual love of God" or the happy contemplation of that natural law which destroyed all individuals. To find the self-preserving man you must take him after he has ceased to grow and before he has begun to love. Self-preservation, being thus no principle of natural history, the facts or estimations classed under that head need to be referred instead to one of two other principles – either to mechanical equilibrium and habit, or to dialectical consistency in judgment.

Self-preservation might express, perhaps, the values which conceived events acquire in respect to a given attitude of will, to an arrested momentary ideal. The actual state of any animal, his given instincts and tensions, are undoubtedly the point of origin from which all changes and relations are morally estimated; and if this attitude is afterward itself subjected to estimation, that occurs by virtue of its affinity or conflict with the living will of another moment. Valuation is dialectical, not descriptive, nor contemplative of a natural process. It might accordingly be developed by seeing what is implied in the self-preservation, or rather expression, of a will which by that dialectic would discover its ideal scope.

Such a principle, however, could never explain the lapse of that attitude itself. A natural process cannot be governed by the ideal relations which conceived things acquire by being represented in one of its moments. Spinoza, however, let himself wander into this path and made the semblance of an attempt, indeed not very deceptive, to trace the sequence of feelings by their mutual implication. The changes in life were to be explained by what the crystallised posture of life might be at a single instant. The arrow's flight was to be deduced from its instantaneous position. A passion's history was to be the history of what would have been its expression if it had had no history at all.

A man suffered by destiny to maintain for ever a single unchanged emotion might indeed think out its multifarious implications much in Spinoza's way. It is in that fashion that parties and sects, when somewhat stable, come to define their affinities and to know their friends and enemies all over the universe of discourse. Suppose, for instance, that I feel some titillation on reading a proposition concerning the contrast between Paul's idea of Peter and

Peter's idea of himself, a titillation which is accompanied by the idea of Spinoza, its external cause. Now he who loves an effect must proportionately love its cause, and titillation accompanied by the idea of its external cause is, Spinoza has proved, what men call love. I therefore find that I love Spinoza. Having got so far, I may consider further, referring to another demonstration in the book, that if some one gives Spinoza joy – Hobbes, for instance – my delight in Spinoza's increased perfection, consequent upon his joy and my love of him, accompanied by the idea of Hobbes, its external cause, constitutes love on my part for the redoubtable Hobbes as well. Thus the periphery of my affections may expand indefinitely, till it includes the infinite, the ultimate external cause of all my titillations. But how these interesting discoveries are interrupted before long by a desire for food, or by an indomitable sense that Hobbes and the infinite are things I do *not* love, is something that my dialectic cannot deduce; for it was the values radiating from a given impulse, the implications of its instant object, that were being explicated, not at all the natural forces that carry a man through that impulse and beyond it to the next phase of his dream, a phase which if it continues the former episode must continue it spontaneously, by grace of mechanical forces.

When dialectic is thus introduced into psychology, an intensive knowledge of the heart is given out for distributive knowledge of events. Such a study, when made by a man of genius, may furnish good spiritual reading, for it will reveal what our passions mean and what sentiments they would lead to if they could remain fixed and dictate all further action. This insight may make us aware of strange inconsistencies in our souls, and seeing how contrary some of our ideals are to others and how horrible, in some cases, would be their ultimate expression, we may be shocked into setting our house in order; and in trying to understand ourselves we may actually develop a self that can be understood. Meantime this inner discipline will not enlighten us about the march of affairs. It will not give us a key to evolution, either in ourselves or in others. Even while we refine our aspirations, the ground they sprang from will be eaten away beneath our feet. Instead of developing yesterday's passion, to-day may breed quite another in its place; and if, having grown old and set in our mental posture, we are incapable of assuming another, and are condemned to carrying on the dialectic of our early visions into a new-born world, to be a schoolmaster's measuring-rod for life's infinite exuberance, we shall find ourselves at once in a foreign country, speaking a language that nobody understands. No destiny is more melancholy than that of the dialectical prophet, who makes more rigid and tyrannous every day a message which every day grows less applicable and less significant.

That remaining portion of psychology which is a science, and a science of matters of fact, is physiological; it belongs to natural history and constitutes the biology of man. Soul, which was not originally distinguished from life, is there studied in its natural operation in the body and in the world. Psychology

then remains what it was in Aristotle's *De Anima* – an ill-developed branch of natural science, pieced out with literary terms and perhaps enriched by occasional dramatic interpretations. The specifically mental or psychic element consists in the feeling which accompanies bodily states and natural situations. This feeling is discovered and distributed at the same time that bodies and other material objects are defined; for when a man begins to decipher permanent and real things, and to understand that they are merely material, he thereby sets apart, in contrast with such external objects, those images and emotions which can no longer enter into the things' texture. The images and emotions remain, however, attached to those things, for they are refractions of them through bodily organs, or effects of their presence on the will, or passions fixed upon them as their object.

In parts of biology which do not deal with man observers do not hesitate to refer in the same way to the pain, the desire, the intention, which they may occasionally read in an animal's aspect. Darwin, for instance, constantly uses psychical language: his birds love one another's plumage and their aesthetic charms are factors in natural selection. Such little fables do not detract from the scientific value of Darwin's observations, because we see at once what the fables mean. The description keeps close enough to the facts observed for the reader to stop at the latter, rather than at the language in which they are stated. In the natural history of man such interpretation into mental terms, such microscopic romance, is even easier and more legitimate, because language allows people, perhaps before their feelings are long past, to describe them in terms which are understood to refer directly to mental experience. The sign's familiarity, to be sure, often hides in these cases a great vagueness and unseizableness in the facts; yet a beginning in defining distinctly the mental phase of natural situations has been made in those small autobiographies which introspective writers sometimes compose, or which are taken down in hospitals and laboratories from the lips of "subjects." What a man under special conditions may say he feels or thinks adds a constituent phase to his natural history; and were these reports exact and extended enough, it would become possible to enumerate the precise sensations and ideas which accompany every state of body and every social situation.

This advantage, however, is the source of that confusion and sophistry which distinguish the biology of man from the rest of physics. Attention is there arrested at the mental term, in forgetfulness of the situation which gave it warrant, and an invisible world, composed of these imagined experiences, begins to stalk behind nature and may even be thought to exist independently. This metaphysical dream may be said to have two stages: the systematic one, which is called idealism, and an incidental one which pervades ordinary psychology, in so far as mental facts are uprooted from their basis and deprived of their expressive or spiritual character, in order to be made elements in a dynamic scheme. This battle of feelings, whether with atoms or

exclusively with their own cohorts, might be called a primitive materialism, rather than an idealism, if idealism were to retain its Platonic sense; for forms and realisations are taken in this system for substantial elements, and are made to figure either as a part or as the whole of the world's matter.

Phenomena specifically mental certainly exist, since natural phenomena and ideal truths are concentrated and telescoped in apprehension, besides being weighted with an emotion due to their effect on the person who perceives them. This variation, which reality suffers in being reported to perception, turns the report into a mental fact distinguishable from its subject-matter. When the flux is partly understood and the natural world has become a constant presence, the whole flux itself, as it flowed originally, comes to be called a mental flux, because its elements and method are seen to differ from the elements and method embodied in material objects or in ideal truth. The primitive phenomena are now called mental because they all deviate from the realities to be ultimately conceived. To call the immediate mental is therefore correct and inevitable when once the ultimate is in view; but if the immediate were all, to call it mental would be unmeaning.

The visual image of a die, for instance, has at most three faces, none of them quite square; no hired artificer is needed to produce it; it cannot be found anywhere nor shaken in any box; it lasts only for an instant; thereafter it disappears without a trace – unless it flits back unaccountably through the memory – and it leaves no ponderable dust or ashes to attest that it had a substance. The opposite of all this is true of the die itself. But were no material die in existence, the image itself would be material; for, however evanescent, it would occupy space, have geometrical shape, colour, and magic dynamic destinies. Its transformations as it rolled on the idea of a table would be transformations in nature, however unaccountable by any steady law. Such material qualities a mental fact can retain only in the spiritual form of representation. A representation of matter is immaterial, but a material image, when no object exists, is a material fact. If the Absolute, to take an ultimate case, perceived nothing but space and atoms (perceiving itself, if you will, therein), space and atoms would be its whole nature, and it would constitute a perfect materialism. The fact that materialism was true would not of itself constitute an idealism worth distinguishing from its opposite. For a vehicle or locus exists only when it makes some difference to the thing it carries, presenting it in a manner not essential to its own nature.

The qualification of being by the mental medium may be carried to any length. As the subject-matter recedes the mental datum ceases to have much similarity or inward relevance to what is its cause or its meaning. The report may ultimately become, like pure pain or pleasure, almost wholly blind and irrelevant to any world; yet such emotion is none the less immersed in matter and dependent on natural changes both for its origin and for its function, since

a significant pleasure or pain makes comments on the world and involves ideals about what ought to be happening there.

Mental facts synchronise with their basis, for no thought hovers over a dead brain and there is no vision in a dark chamber; but their tenure of life is independent of that of their objects, since thought may be prophetic or reminiscent and is intermittent even when its object enjoys a continuous existence. Mental facts are similar to their objects, since things and images have, intrinsically regarded, the same constitution; but images do not move in the same plane with things and their parts are in no proportionate dynamic relation to the parts of the latter. Thought's place in nature is exiguous, however broad the landscape it represents; it touches the world tangentially only, in some ferment of the brain. It is probably no atom that supports the soul (as Leibnitz imagined), but rather some cloud of atoms shaping or remodelling an organism. Mind in this case would be, in its physical relation to matter, what it feels itself to be in its moral attitude toward the same; a witness to matter's interesting aspects and a realisation of its forms.

Mental facts, moreover, are highly selective; especially does this appear in respect to the dialectical world, which is in itself infinite, while the sum of human logic and mathematics, though too long for most men's patience, is decidedly brief. If we ask ourselves on what principle this selection and foreshortening of truth takes place in the mind, we may perhaps come upon the real bond and the deepest contrast between mind and its environment. The infinity of formal truth is disregarded in human thought when it is irrelevant to practice and to happiness; the infinity of nature is represented there in violent perspective, centring about the body and its interests. The seat and starting-point of every mental survey is a brief animal life. A mind seems, then, to be a consciousness of the body's interests, expressed in terms of what affects that body, as if in the Babel of nature a man heard only the voices that pronounced his name. A mind is a private view; it is gathered together in proportion as physical sensibility extends its range and makes one stretch of being after another tributary to the animal's life, and in proportion also as this sensibility is integrated, so that every organ in its reaction enlists the resources of every other organ as well. A personal will and intelligence thus arise; and they direct action from within with a force and freedom which are exactly proportionate to the material forces, within and without the body, which the soul has come to represent.

In other words, mind raises to an actual existence that *form* in material processes which, had the processes remained wholly material, would have had only ideal or imputed being – as the stars would not have been divided into the signs of the Zodiac but for the fanciful eye of astrologers. Automata might arise and be destroyed without any value coming or going; only a form-loving observer could say that anything fortunate or tragic had occurred, as poets might at the budding or withering of a flower. Some of nature's automata,

however, love themselves, and comment on the form they achieve or abandon; these constellations of atoms are genuine beasts. Their consciousness and their interest in their own individuality rescues that individuality from the realm of discourse and from having merely imputed limits.

That the basis of mind lies in the body's interests rather than in its atoms may seem a doctrine somewhat too poetical for psychology; yet may not poetry, superposed on material existence and supported by it, be perhaps the key to mind? Such a view hangs well together with the practical and prospective character of consciousness, with its total dependence on the body, its cognitive relevance to the world, and its formal disparity from material being. Mind does not accompany body like a useless and persistent shadow; it is significant and it is intermittent. Much less can it be a link in physiological processes, processes irrelevant to its intent and incompatible with its immaterial essence. Consciousness seems to arise when the body assumes an attitude which, being an attitude, supervenes upon the body's elements and cannot be contained within them. This attitude belongs to the whole body in its significant operation, and the report of this attitude, its expression, requires survey, synthesis, appreciation – things which constitute what we call mentality. This remains, of course, the mentality of that material situation; it is the voice of that particular body in that particular pass. The mind therefore represents its basis, but this basis (being a *form* of material existence and not matter itself) is neither vainly reduplicated by representation nor used up materially in the process.

Representation is far from idle, since it brings to focus those mechanical unities which otherwise would have existed only potentially and at the option of a roving eye. In evoking consciousness nature makes this delimination real and unambiguous; there are henceforth actual centres and actual interests in the mechanical flux. The flux continues to be mechanical, but the representation of it supervening has created values which, being due to imputation, could not exist without being imputed, while at the same time they could not have been imputed without being attached to one object or event rather than to another. Material dramas are thus made moral and raised to an existence of their own by being expressed in what we call the souls of animals and men; a mind is the entelechy of an organic body.[1] It is a region where form breeds an existence to express it, and destiny becomes important by being felt. Mind adds to being a new and needful witness so soon as the constitution of being gives foothold to apperception of its movement, and offers something in which it is possible to ground an interest.

[1] Aristotle called the soul the first entelechy of such a body. This first entelechy is what we should call life, since it is possessed by a man asleep. The French I know but do not use is in its first entelechy; the French I am actually speaking is in its second. Consciousness is therefore the second or actualised entelechy of its body.

That Aristotle has not been generally followed in views essentially so natural and pregnant as these is due no doubt to want of thoroughness in conceiving them, not only on the part of his readers but even on his own part; for he treated the soul, which should be on his own theory only an expression and an unmoved mover, as a power and an efficient cause. Analysis had not gone far enough in his day to make evident that all dynamic principles are mechanical and that mechanism can obtain only among objects; but by this time it should no longer seem doubtful that mental facts can have no connection except through their material basis and no mutual relevance except through their objects.

There is indeed a strange half-assumption afloat, a sort of reserved faith which every one seems to respect but nobody utters, to the effect that the mental world has a mechanism of its own, and that ideas intelligently produce and sustain one another. Systematic idealists, to be sure, have generally given a dialectical or moral texture to the cosmos, so that the passage from idea to idea in experience need not be due, in their physics, to any intrinsic or proportionate efficacy in these ideas themselves. The march of experience is not explained at all by such high cosmogonies. They abandon that practical calculation to some science of illusion that has to be tolerated in this provisional life. Their own understanding is of things merely in the gross, because they fall in with some divine plan and produce, unaccountably enough, some interesting harmony. Empirical idealists, on the contrary, in making a metaphysics out of psychology, hardly know what they do. The laws of experience which they refer to are all laws of physics. It is only the "possibilities" of sensation that stand and change according to law; the sensations themselves, if not referred to those permanent possibilities, would be a chaos worse than any dream.

Correct and scrupulous as empiricism may be when it turns its face backward and looks for the seat, the criterion, and the elements of knowledge, it is altogether incoherent and self-inhibited when it looks forward. It can believe in nothing but in what it conceives, if it would rise at all above a stupid immersion in the immediate; yet the relations which attach the moments of feeling together are material relations, implying the whole frame of nature. Psychology can accordingly conceive nothing but the natural world, with its diffuse animation, since this is the only background that the facts suggest or that, in practice, anybody can think of. If empiricism trusted the intellect, and consented to immerse flying experience in experience understood, it would become ordinary science and ordinary common sense. Deprecating this result, for no very obvious reason, it has to balance itself on the thin edge of an unwilling materialism, with a continual protestation that it does not believe in anything that it thinks. It is wholly entangled in the prevalent sophism that a man must renounce a belief when he discovers how he has formed it, and that our ancestors – at least the remoter ones – begin to exist when we discover them.

When Descartes, having composed a mechanical system of the world, was asked by admiring ladies to say something about the passions, what came into his mind was characteristically simple and dialectical. Life, he thought, was a perpetual conflict between reason and the emotions. The soul had its own natural principle to live by, but was diverted from that rational path by the waves of passion that beat against it and sometimes flooded it over. That was all his psychology. Ideal entities in dramatic relations, in a theatre which had to be borrowed, of course, from the other half of the world; because while a material mechanism might be conceived without minds in it, minds in action could not be conceived without a material mechanism – at least a represented one – lying beneath and between. Spinoza made a great improvement in the system by attaching the mind more systematically to the body, and studying the parts which organ and object played in qualifying knowledge; but his conception of mental unities and mental processes remained literary, or at best, as we have seen, dialectical. No shadow of a principle at once psychic and genetic appeared in his philosophy. All mind was still a transcript of material facts or a deepening of moral relations.

The idea of explaining the flow of ideas without reference to bodies appeared, however, in the principle of association. This is the nearest approach that has yet been made to a physics of disembodied mind – something which idealism sadly needs to develop. A terrible incapacity, however, appears at once in the principle of association; for even if we suppose that it could account for the flow of ideas, it does not pretend to supply any basis for sensations. And as the more efficient part of association – association by contiguity – is only a repetition in ideas of the order once present in impressions, the whole question about the march of mental experience goes back to what association does not touch, namely, the origin of sensations. What everybody assumed, of course, was that the order and quality of sensations were due to the body; but their derivation was not studied. Hume ignored it as much as possible, and Berkeley did not sacrifice a great deal when he frankly suggested that the production of sensation must be the direct work of God.

This tendency not to recognise the material conditions of mind showed itself more boldly in the treatment of ideation. We are not plainly aware (in spite of headaches, fatigue, sleep, love, intoxication, and madness) that the course of our thoughts is as directly dependent on the body as is their inception. It was therefore possible, without glaring paradox, to speak as if ideas caused one another. They followed, in recurring, the order they had first had in experience, as when we learn something by heart. Why, a previous verse being given, we should sometimes be unable to repeat the one that had often followed it before, there was no attempt to explain: it sufficed that reverie often seemed to retrace events in their temporal order. Even less dependent on material causes seemed to be the other sort of association, association by

similarity. This was a feat for the wit and the poet, to jump from China to Peru, by virtue of some spark of likeness that might flash out between them.

Much natural history has been written and studied with the idea of finding curious facts. The demand has not been for constant laws or intelligibility, but for any circumstance that could arrest attention or divert the fancy. In this spirit, doubtless, instances of association were gathered and classified. It was the young ladies' botany of mind. Under association could be gathered a thousand interesting anecdotes, a thousand choice patterns of thought. Talk of the wars, says Hobbes, once led a man to ask what was the value of a Roman penny. But why only once? The wars must have been often mentioned when the delivering up of King Charles did not enter any mind; and when it did, this would not have led any one to think of Judas and the thirty pence, unless he had been a good royalist and a good Christian – and then only by a curious accident. It was not these ideas, then, in their natural capacity that suggested one another; but some medium in which they worked, once in the world, opened those particular avenues between them. Nevertheless, no one cared to observe that each fact had had many others, never recalled, associated with it as closely as those which were remembered. Nor was the matter taken so seriously that one needed to ask how, among all similar things, similarity could decide which should be chosen; nor how among a thousand contiguous facts one rather than another should be recalled for contiguity's sake.

The best instance, perhaps, of regular association might be found in language and its meaning; for understanding implies that each word habitually calls up its former associates. Yet in what, psychologically considered, does understanding a word consist? What concomitants does the word "horse" involve in actual sentience? Hardly a clear image such as a man might paint; for the name is not confined to recalling one view of one animal obtained at one moment. Perhaps all that recurs is a vague sense of the environment, in nature and in discourse, in which that object lies. The word "kite" would immediately make a different region warm in the world through which the mind was groping. One would turn in idea to the sky rather than to the ground, and feel suggestions of a more buoyant sort of locomotion.

Understanding has to be described in terms of its potential outcome, since the incandescent process itself, as it exists in transit, will not suffer stable terms to define it. Potentiality is something which each half of reality reproaches the other with; things are potential to feeling because they are not life, and feelings are potential to science because they elude definition. To understand, therefore, is to know what to do and what to say in the sign's presence; and this practical knowledge is far deeper than any echo casually awakened in fancy at the same time. Instinctive recognition has those echoes for the most superficial part of its effect. Because I understand what "horse" means, the word can make me recall some episode in which a horse once figured. This

understanding is instinctive and practical and, if the phrase may be pardoned, it is the body that understands. It is the body, namely, that contains the habit and readiness on which understanding hangs; and the sense of understanding, the instant rejection of whatever clashes and makes nonsense in that context, is but a transcript of the body's education. Actual mind is all above board; it is all speculative, vibrant, the fruit and gift of those menial subterranean processes. Some generative processes may be called psychic in that they minister to mind and lend it what little continuity it can boast of; but they are not processes in consciousness. Processes in consciousness are aesthetic or dialectical processes, focussing a form rather than ushering in an existence. Mental activity has a character altogether alien to association: it is spiritual, not mechanical; an entelechy, not a genesis.

For these and other reasons association has fallen into some disrepute; but it is not easy to say what, in absolute psychology, has come to take its place. If we speak of suggestion, a certain dynamic turn seems to be given to the matter; yet in what sense a perception suggests its future development remains a mystery. That a certain ripening and expansion of consciousness goes on in man, not guided by former collocations of ideas, is very true; for we do not fall in love for the first time because this person loved and these ardent emotions have been habitually associated in past experience. And any impassioned discourse, opening at every turn into new vistas, shows the same sort of vegetation. Yet to observe that consciousness is automatic is not to disclose the mechanism by which it evolves. The theory of spontaneous growth offers less explanation of events, if that be possible, than the theory of association. It is perhaps a better description of the facts, since at least it makes no attempt to deduce them from one another.

If, on the contrary, a relation implied in the burden or will of the moment be invoked, the connection established, so far as it goes, is dialectical. Where a dialectical correspondence is not found, a material cause would have to be appealed to. Such a half-dialectical psychology would be like Schopenhauer's, quite metaphysical. It might be a great improvement on an absolute psychology, because it would restore, even if in mythical terms, a background and meaning to life. The unconscious Absolute Will, the avid Genius of the Species, the all-attracting Platonic Ideas are fabulous; but beneath them it is not hard to divine the forces of nature. This volitional school supplies a good stepping-stone from metaphysics back to scientific psychology. It remains merely to substitute instinct for will, and to explain that instinct – or even will, if the term be thought more consoling – is merely a word covering that operative organisation in the body which controls action, determines affinities, dictates preferences, and sustains ideation.

What scientific psychology has to attempt – for little has been accomplished – may be reduced to this: To develop physiology and anthropology until the mechanism of life becomes clear, at least in its general method, and

then to determine, by experiment and by well-sifted testimony, what conscious sublimation each of those material situations attains, if indeed it attains any. There will always remain, no doubt, many a region where the machinery of nature is too fine for us to trace or eludes us by involving agencies that we lack senses to perceive. In these regions where science is denied we shall have to be satisfied with landscape-painting. The more obvious results and superficial harmonies perceived in those regions will receive names and physics will be arrested at natural history. Where these unexplained facts are mental it will not be hard to do more systematically what common sense has done already, and to attach them, as we attach love or patriotism, to the natural crises that subtend them.

This placing of mental facts is made easy by the mental facts themselves, since the connection of mind with nature is double, and even when the derivation of a feeling is obscure we have but to study its meaning, allowing it to tell us what it is interested in, for a roundabout path to lead us safely back to its natural basis. It is superfluous to ask a third person what circumstances produce hunger: hunger will lead you unmistakably enough to its point of origin, and its extreme interest in food will not suffer you long to believe that want of nourishment has nothing to do with its cause. And it is not otherwise with higher emotions and ideas. Nothing but sophistry can put us in doubt about what conscience represents; for conscience does not say, square the circle, extinguish mankind so as to stop its sufferings, or steal so as to benefit your heirs. It says, Thou shalt not kill, and it also says, Thou shalt worship the Lord thy God who brought thee out of the land of Egypt. So that conscience, by its import and incidence, clearly enough declares what it springs from – a social tradition; and what it represents – the interests, real or imaginary, of the community in which you were reared.

Where psychology depends on literature, where both its units and its method are poetical, there can be no talk of science. We may as justly, or as absurdly, speak of the spirit of an age or of a religion as of a man's character or a river's god. Particulars in illustration may have good historic warrant, but the unities superimposed are ideal. Such metaphors may be very useful, for a man may ordinarily be trusted to continue his practices and a river its beneficent or disastrous floods; and since those rhetorical forms have no existence in nature we may continue to frame them as may be most convenient for discourse.

When psychology is a science, then, it describes the flying consciousness that accompanies bodily life. It is the science of feeling or absolute appearance, taken exactly as it seems or feels. Does such a psychology, we may be tempted to ask, constitute scientific knowledge of reality? Is it at last the true metaphysics? This question would have to be answered in the negative, yet not without some previous discriminations. There is honesty in the conviction that sentience is a sort of absolute; it is something which certainly exists. The

first Cartesian axiom applies to it, and to feel, even doubtfully, that feeling existed would be to posit its existence. The science that describes sentience describes at least a part of existence. Yet this self-grounding of consciousness is a suspicious circumstance: it renders it in one sense the typical reality and in another sense perhaps the sorriest illusion.

"Reality" is an ambiguous term. If we mean by it the immediate, then sentience would be a part if not the whole of reality; for what we mean by sentience or consciousness is the immediate in so far as we contain it, and whatever self-grounded existence there may be elsewhere can be conceived by us only mythically and on that analogy, as if it were an extension or variation of sentience. Psychology would then be knowledge of reality, for even when consciousness contains elaborate thoughts that might be full of illusions, psychology takes them only as so much feeling, and in that capacity they are real enough. At the same time, while our science terminates upon mere feeling, it can neither discover nor describe that feeling except in terms of something quite different; and the only part of psychology that perhaps penetrates to brute sentience is the part that is not scientific. The knowledge that science reaches about absolute states of mind is relative knowledge; these states of mind are approached from without and are defined by their surrounding conditions and by their ideal objects. They are known by being enveloped in processes of which they themselves are not aware. Apart from this setting, the only feeling known is that which is endured. After the fact, or before, or from any other point of vantage, it cannot be directly revealed; at best it may be divined and re-enacted. Even this possible repetition would not constitute knowledge unless the imaginative reproduction were identified with or attributed to some natural fact; so that an adventitious element would always attach to any recognised feeling, to any feeling reported to another mind. It could not be known at all unless something were known about it, so that it might not pass, as otherwise it would, for a mere ingredient of present sentience.

It is precisely by virtue of this adventitious element that the re-enacted feeling takes its place in nature and becomes an object of knowledge. Science furnishes this setting; the jewel – precious or false – must be supplied by imagination. Romance, dramatic myth, is the only instrument for knowing this sort of "reality." A flying moment, if at all *understood* or underpinned, or if seen in its context, would be not known absolutely as it had been felt, but would be known scientifically and as it lay in nature. But dramatic insight, striving to pierce through the machinery of the world and to attain and repeat what dreams may be going on at its core, is no science; and the very notion that the dreams are internal, that they make the interior or substance of bodies, is a crude materialistic fancy. Body, on the contrary, is the substance or instrument of mind, and has to be looked for beneath it. The mind is itself ethereal and plays about the body as music about a violin, or rather as the

sense of a page about the print and paper. To look for it *within* is not to understand what we are looking for.

Knowledge of the immediate elsewhere is accordingly visionary in its method, and furthermore, if, by a fortunate chance, it be true in fact, it is true only of what in itself is but appearance; for the immediate, while absolutely real in its stress or presence, is indefinitely ignorant and false in its deliverance. It knows itself, but in the worst sense of the word knowledge; for it knows nothing of what is true about it, nothing of its relations and conditions. To pierce to this blind "reality" or psychic flux, which is nothing but flying appearance, we must rely on fortune, or an accidental harmony between imitative fancy in us now and original sentience elsewhere. It is accordingly at least misleading to give the name of "reality" to this appearance, which is entirely lost and inconsequential in its being, without trace of its own status, and consequently approachable or knowable only by divination, as a dream might call to another dream.

It is preferable to give a more Platonic meaning to the word and to let "reality" designate not what is merely felt diffusely but what is true about those feelings. Then dramatic fancy, psychology of the sympathetic sort, would not be able to reach reality at all. On the other hand scientific psychology, together with all other sciences, would have reality for its object; for it would disclose what really was true about sentient moments, without stopping particularly to sink abstractedly into their inner quality or private semblance. It would approach and describe the immediate as a sentient factor in a natural situation, and show us to what extent that situation was represented in that feeling. This representation, by which the dignity and interest of pure sentience would be measured, might be either pictorial or virtual; that is, a conscious moment might represent the environing world either scientifically, by understanding its structure, or practically, by instinctive readiness to meet it.

What, for instance, is the reality of Napoleon? Is it what a telepathic poet, a complete Browning, might reconstruct? Is it Napoleon's life-long soliloquy? Or to get at the reality should we have to add, as scientific psychology would, the conditions under which he lived, and their relation to his casual feelings? Obviously if Napoleon's thoughts had had no reference to the world we should not be able to recover them; or if by chance such thoughts fell some day to our share, we should attribute them to our own mental luxuriance, without suspecting that they had ever visited another genius. Our knowledge of his life, even where it is imaginative, depends upon scientific knowledge for its projection; and his fame and immortality depend on the degree to which his thoughts, being rooted in the structure of the world and pertinent to it, can be rationally reproduced in others and attributed to him. Napoleon's consciousness might perhaps be more justly identified with the truth or reality of him than could that of most people, because he seems to have been

unusually cognisant of his environment and master of the forces at work in it and in himself. He understood his causes and function, and knew that he had *arisen*, like all the rest of history, and that he stood for the transmissible force and authority of greater things. Such a consciousness can be known in proportion as we, too, possess knowledge, and is worth the pains; something which could not be said of the absolute sentience of Dick or Harry, which has only material being, brute existence, without relevance to anything nor understanding of itself.

The circumstances, open to science, which surround consciousness are thus real attributes of a man by which he is truly known and distinguished. Appearances are the qualities of reality, else realities would be without place, time, character, or interrelation. In knowing that Napoleon was a Corsican, a short man with a fine countenance, we know appearances only; but these appearances are true of the reality. And if the presumable inner appearances, Napoleon's long soliloquy, were separated from the others, those inner appearances would not belong to Napoleon nor have any home in the knowable world. That which physics, with its concomitant psychology, might discover in a man is the sum of what is true about him, seeing that a man is a concretion in existence, the fragment of a world, and not a definition. Appearances define the constituent elements of his reality, which could not be better known than through their means.

THE VALIDITY OF SCIENCE

George Santayana. "The Validity of Science." *The Life of Reason*, vol. 5: *Reason in Science* (New York: Charles Scribner's Sons, 1906), chap. 11, pp. 301–320.

The same despair or confusion which, when it overtakes human purposes, seeks relief in arbitrary schemes of salvation, when it overtakes human knowledge, may breed arbitrary substitutes for science. There are post-rational systems of nature as well as of duty. Most of these are myths hardly worth separating from the post-rational moralities they adorn, and have been sufficiently noticed in the last chapter; but a few aspire to be critical revisions of science, themselves scientific. It may be well, in bringing this book to a close, to review these proposed revisions. The validity of science is at stake, and with it the validity of that whole Life of Reason which science crowns, and justifies to reflection.

There are many degrees and kinds of this critical retractation. Science may be accepted bodily, while its present results are modified by suggesting speculatively what its ultimate results might be. This is natural philosophy or legitimate metaphysics. Or science may be accepted in part, and in part subjected to control by some other alleged vehicle of knowledge. This is traditional or intuitive theology. Or science may be retracted and withdrawn altogether, on the ground that it is but methodological fiction, its facts appearances merely, and its principles tendencies to feign. This is transcendentalism; whereupon a dilemma presents itself. We may be invited to abstain from all hypostasis or hearty belief in anything, and to dwell only on the consciousness of imaginative activity in a vacuum – which is radical idealism. Or we may be assured that, science being a dream, we may awake from it into another cosmos, built upon principles quite alien to those illustrated in nature or applicable in practice – which is idealism of the mythical sort. Finally it may occur to us that the criticism of science is an integral part of science itself, and that a transcendental method of survey, which marshals all things in the order of their discovery, far from invalidating knowledge can only serve to separate it from incidental errors and to disclose the relative importance of truths. Science would then be rehabilitated by criticism. The primary movement of the intellect would not be condemned by that subsequent reflection which it makes possible, and which collates its results. Science, purged of all needless realism and seen in its relation to human life,

would continue to offer the only conception of reality which is pertinent or possible to the practical mind.

We may now proceed to discuss these various attitudes in turn.

A first and quite blameless way of criticising science is to point out that science is incomplete. That it grows fast is indeed its commonest boast; and no man of science is so pessimistic as to suppose that its growth is over. To wish to supplement science and to regard its conclusions as largely provisional is therefore more than legitimate. It is actually to share the spirit of inquiry and to feel the impulse toward investigation. When new truths come into view, old truths are thereby reinterpreted and put in a new light; so that the acquisitions of science not only admit of revision but loudly call for it, not wishing for any other authority or vindication than that which they might find in the context of universal truth.

To revise science in this spirit would be merely to extend it. No new method, no transverse philosophy, would be requisite or fitted for the task. Knowledge would be transformed by more similar knowledge, not by some verbal manipulation. Yet while waiting for experience to grow and accumulate its lessons, a man of genius, who had drunk deep of experience himself, might imagine some ultimate synthesis. He might venture to carry out the suggestions of science and anticipate the conclusions it would reach when completed. The game is certainly dangerous, especially if the prophecy is uttered with any air of authority; yet with good luck and a fine instinct, such speculation may actually open the way to discovery and may diffuse in advance that virtual knowledge of physics which is enough for moral and poetic purposes. Verification in detail is needed, not so much for its own sake as to check speculative errors; but when speculation is by chance well directed and hits upon the substantial truth, it does all that a completed science would do for mankind; since science, if ever completed, would immediately have to be summed up again and reduced to generalities. Under the circumstances of human life, ultimate truth must forego detailed verification and must remain speculative. The curse of modern philosophy is only that it has not drawn its inspiration from science; as the misfortune of science is that it has not yet saturated the mind of philosophers and recast the moral world. The Greek physicists, puerile as was their notion of natural mechanism, had a more integral view of things. They understood nature's uses and man's conditions in an honest and noble way. If no single phenomenon had been explained correctly by any philosopher from Thales to Lucretius, yet by their frank and studious contemplation of nature they would have liberated the human soul.

Unfortunately the supplements to science which most philosophers supply in our day are not conceived in a scientific spirit. Instead of anticipating the physics of the future they cling to the physics of the past. They do not stimulate us by a picture, however fanciful, of what the analogies of nature and politics actually point to; they seek rather to patch and dislocate current

physics with some ancient myth, once the best physics obtainable, from which they have not learned to extricate their affections.

Sometimes these survivals are intended to modify scientific conceptions but slightly, and merely to soften a little the outlines of a cosmic picture to which religion and literature are not yet accustomed. There is a school of political conservatives who, with no specific interest in metaphysics, cannot or dare not break with traditional modes of expression, with the customs of their nation, or with the clerical classes. They accordingly append to current knowledge certain sentimental postulates, alleging that what is established by tradition and what appeals to the heart must somehow correspond to something which is needful and true. But their conventional attachment to a religion which in its original essence was perhaps mystical and revolutionary, scarcely modifies, in their eyes, the sum of practical assurances or the aim of human life. As language exercises some functions which science can hardly assume (as, for instance, in poetry and communication) so theology and metaphysics, which to such men are nothing but languages, might provide for inarticulate interests, and unite us to much that lies in the dim penumbra of our workaday world. Ancient revelations and mysteries, however incredible if taken literally, might therefore be suffered to nourish undisturbed, so long as they did not clash with any clear fact or natural duty. They might continue to decorate with a mystical aureole the too prosaic kernel of known truth.

Mythology and ritual, with the sundry divinations of poets, might in fact be kept suspended with advantage over human passion and ignorance, to furnish them with decent expression. But once indulged, divination is apt to grow arrogant and dogmatic. When its oracles have become traditional they are almost inevitably mistaken for sober truths. Hence the second kind of supplement offered to science, so that revelations with which moral life has been intertwined may find a place beside or beyond science. The effort is honest, but extraordinarily short-sighted. Whatever value those revelations may have they draw from actual experience or inevitable ideals. When the ground of that experience and those ideals is disclosed by science, nothing of any value is lost; it only remains to accustom ourselves to a new vocabulary and to shift somewhat the associations of those values which life contains or pursues. Revelations are necessarily mythical and subrational; they express natural forces and human interests in a groping way, before the advent of science. To stick in them, when something more honest and explicit is available, is inconsistent with caring for attainable welfare or understanding the situation. It is to be stubborn and negligent under the cloak of religion. These prejudices are a drag on progress, moral no less than material; and the sensitive conservatism that fears they may be indispensable is entangled in a pathetic delusion. It is conservatism in a ship-wreck. It has not the insight to embrace the fertile principles of life, which are always ready to renew life after no matter what natural catastrophe. The good laggards have no courage to

strip for the race. Rather than live otherwise, and live better, they prefer to nurse the memories of youth and to die with a retrospective smile upon their countenance.

Far graver than the criticism which shows science to be incomplete is that which shows it to be relative. The fact is undeniable, though the inferences made from it are often rash and gratuitous. We have seen that science is nothing but developed perception, interpreted intent, common-sense rounded out and minutely articulated. It is therefore as much an instinctive product, as much a stepping forth of human courage in the dark, as is any inevitable dream or impulsive action. Like life itself, like any form of determinate existence, it is altogether autonomous and unjustifiable from the outside. It must lean on its own vitality; to sanction reason there is only reason, and to corroborate sense there is nothing but sense. Inferential thought is a venture not to be approved of, save by a thought no less venturesome and inferential. This is once for all the fate of a living being – it is the very essence of spirit – to be ever on the wing, borne by inner forces toward goals of its own imagining, confined to a passing apprehension of a represented world. Mind, which calls itself the organ of truth, is a permanent possibility of error. The encouragement and corroboration which science is alleged to receive from moment to moment may, for aught it knows, be simply a more ingenious self-deception, a form of that cumulative illusion by which madness can confirm itself, creating a whole world, with an endless series of martyrs, to bear witness to its sanity.

To insist on this situation may seem idle, since no positive doctrine can gain thereby in plausibility, and no particular line of action in reasonableness. Yet this transcendental exercise, this reversion to the immediate, may be recommended by way of a cathartic, to free the mind from ancient obstructions and make it hungrier and more agile in its rational faith. Scepticism is harmless when it is honest and universal; it clears the air and is a means of reorganising belief on its natural foundations. Belief is an inevitable accompaniment of practice and intent, both of which it will cling to all the more closely after a thorough criticism. When all beliefs are challenged together, the just and necessary ones have a chance to step forward and to re-establish themselves alone. The doubt cast on science, when it is an ingenuous and impartial doubt, will accordingly serve to show what sort of thing science is, and to establish it on a sure foundation. Science will then be seen to be tentative, genial, practical, and humane, full of ideality and pathos, like every great human undertaking.

Unfortunately a searching disintegration of dogma, a conscientious reversion to the immediate, is seldom practised for its own sake. So violent a disturbance of mental habits needs some great social upheaval or some revolutionary ambition to bring it about. The transcendental philosophy might never have been put forward at all, had its authors valued it for what

it can really accomplish. The effort would have seemed too great and the result too nugatory. Their criticism of knowledge was not freely undertaken, with the pure speculative motive of understanding and purifying human science. They were driven on by the malicious psychology of their predecessors, by the perplexities of a sophistical scepticism, and by the imminent collapse of traditional metaphysics. They were enticed at the same time by the hope of finding a new basis for the religious myths associated with that metaphysics. In consequence their transcendentalism was not a rehearsal of the Life of Reason, a retrospect criticising and justifying the phases of human progress. It was rather a post-rational system of theology, the dangerous cure to a harmless disease, inducing a panic to introduce a fable. The panic came from the assumption (a wholly gratuitous one) that a spontaneous constructive intellect cannot be a trustworthy instrument, that appearances cannot be the properties of reality, and that things cannot be what science finds that they are. We were forbidden to believe in anything we might discover or to trust in anything we could see. The artificial vacuum thus produced in the mind ached to be filled with something, and of course a flood of rhetorical commonplaces was at hand, which might rush in to fill it.

The most heroic transcendentalists were but men, and having imagined that logic obliged them to abstain from every sort of hypostasis, they could not long remain true to their logic. For a time, being of a buoyant disposition, they might feel that nothing could be more exhilarating than to swim in the void, altogether free from settled conditions, altogether the ignorant creators of each moment's vision. Such a career evidently affords all sorts of possibilities, except perhaps the possibility of being a career. But when a man has strained every nerve to maintain an absolute fluidity and a painful fidelity to the immediate, he can hardly be blamed if he lapses at last into some flattering myth, and if having satisfied himself that all science is fiction he proclaims some fairy-tale to be the truth. The episodes of experience, not being due to any conceivable machinery beneath, might come of mere willing, or at the waving of a dialectical wand. Yet apart from this ulterior inconsistency and backsliding into credulity, transcendentalism would hear nothing of causes or grounds. All phenomena existed for it on one flat level. We were released from all dogma and reinstated in the primordial assurance that we were all there was, but without understanding what we were, and without any means of controlling our destiny, though cheered by the magnificent feeling that that destiny was great.

It is intelligible that a pure transcendentalism of this sort should not be either stable or popular. It may be admired for its analytic depth and its persistency in tracing all supposed existences back to the experience that vouches for them. Yet a spirit that finds its only exercise in gloating on the consciousness that it is a spirit, one that has so little skill in expression that it feels all its embodiments to be betrayals and all its symbols to be misrepresentations, is

a spirit evidently impotent and confused. It is self-inhibited, and cannot fulfil its essential vocation by reaching an embodiment at once definitive and ideal, philosophical and true. We may excuse a school that has done one original task so thoroughly as transcendentalism has thing could be said of it, would be simply an integral term in the discourse that described it. And this discourse, this sad residuum of reality, would remain an absolute datum without a ground, without a subject-matter, without a past, and without a future.

It suffices, therefore, to take the supposed negative implication in transcendentalism a little seriously to see that it leaves nothing standing but negation and imbecility; so that we may safely conclude that such a negative implication is gratuitous, and also that in taking the transcendental method for an instrument of reconstruction its professors were radically false to it. They took the starting-point of experience, on which they had fallen back, for its ultimate deliverance, and in reverting to protoplasm they thought they were rising to God. The transcendental method is merely retrospective; its use is to recover more systematically conceptions already extant and inevitable. It invalidates nothing in science; much less does it carry with it any rival doctrine of its own. Every philosophy, even materialism, may find a transcendental justification, if experience as it develops will yield no other terms. What has reason to tremble at a demand for its credentials is surely not natural science; it is rather those mystical theologies or romantic philosophies of history which aspire to take its place. Such lucubrations, even if reputed certain, can scarcely be really credited or regarded in practice; while scientific tenets are necessarily respected, even when they are declared to be fictions. This nemesis is inevitable; for the mind must be inhabited, and the ideas with which science peoples it are simply its involuntary perceptions somewhat more clearly arranged.

That the relativity of science – its being an emanation of human life – is nothing against its truth appears best, perhaps, in the case of dialectic. Dialectic is valid by virtue of an intended meaning and felt congruity in its terms; but these terms, which intent fixes, are external and independent in their ideal nature, and the congruity between them is not created by being felt but, whether incidentally felt or not, is inherent in their essence. Mathematical thinking is the closest and most intimate of mental operations, nothing external being called in to aid; yet mathematical truth is as remote as possible from being personal or psychic. It is absolutely self-justified and is necessary before it is discovered to be so. Here, then, is a conspicuous region of truth, disclosed to the human intellect by its own internal exercise, which is nevertheless altogether independent, being eternal and indefeasible, while the thought that utters it is ephemeral.

The validity of material science, not being warranted by pure insight, cannot be so quickly made out; nevertheless it cannot be denied systematically,

and the misunderstood transcendentalism which belittles physics contradicts its own basis. For how are we supposed to know that what call facts are mere appearances and what we call objects mere creations of thought? We know this by physics. It is physiology, a part of physics, that assures us that our senses and brains are conditions of our experience. Were it not for what we know of the outer world and of our place in it, we should be incapable of attaching any meaning to subjectivity. The flux of things would then go on in their own medium, not in our minds; and no suspicion of illusion or of qualification by mind would attach to any event in nature. So it is in a dream; and it is our knowledge of physics, our reliance on the world's material coherence, that marks our awakening, and that constitutes our discovery that we exist as minds and are subject to dreaming. It is quite true that the flux, as it exists in men, is largely psychic; but only because the events it contains are effects of material causes and the images in it are flying shadows cast by solid external things. This is the meaning of psychic existence, and its differentia. Mind is an expression, weighted with emotion, of mechanical relations among bodies. Suppose the bodies all removed: at once the images formerly contrasted with those bodies would resume their inherent characteristics and mutual relation; they would become existences in their own category, large, moving, coloured, distributed to right and left; that is, save for their values, they would become material things.

Physics is accordingly a science which, though hypothetical and only verifiable by experiment, is involved in history and psychology and therefore in any criticism of knowledge. The contradiction would be curious if a man should declare that his ideas were worthless, being due to his organs of sense, and that therefore these organs (since he had an idea of them) did not exist. Yet on this brave argument idealism chiefly rests. It asserts that bodies are mere ideas, because it is through our bodies that we perceive them. When physics has discovered the conditions under which knowledge of physics has arisen, physics is supposed to be spirited away; whereas, of course, it has only closed its circle and justified its sovereignty. Were all science retracted and reduced to symbolic calculation nothing would remain for this calculation to symbolise. The whole force of calling a theory merely a vehicle or method of thought, leading us to something different from itself, lies in having a literal knowledge of this other thing. But such literal knowledge is the first stage of science, which the other stages merely extend. So that when, under special circumstances, we really appeal to algebraic methods of expression and think in symbols, we do so in the hope of transcribing our terms, when the reckoning is over, into the language of familiar facts. Were these facts not forthcoming, the symbolic machinery would itself become the genuine reality – since it is really given – and we should have to rest in it, as in the ultimate truth. This is what happens in mythology, when the natural phenomena expressed by it are forgotten. But natural phenomena themselves are symbols

of nothing, because they are primary data. They are the constitutive elements of the reality they disclose.

The validity of science in general is accordingly established merely by establishing the truth of its particular propositions, in dialectic on the authority of intent and in physics on that of experiment. It is impossible to base science on a deeper foundation or to override it by a higher knowledge. What is called metaphysics, if not an anticipation of natural science, is a confusion of it with dialectic or a mixture of it with myths. If we have the faculty of being utterly sincere and of disintegrating the conventions of language and religion, we must confess that knowledge is only a claim we put forth, a part of that unfathomable compulsion by force of which we live and hold our painted world together for a moment. If we have any insight into mind, or any eye for human history, we must confess at the same time that the oracular substitutes for knowledge to which, in our perplexities, we might be tempted to fly, are pathetic popular fables, having no other sanctity than that which they borrow from the natural impulses they play upon. To live by science requires intelligence and faith, but not to live by it is folly.

If science thus contains the sum total of our rational convictions and gives us the only picture of reality on which we should care to dwell, we have but to consult the sciences in detail to ascertain, as far as that is possible, what sort of a universe we live in. The result is as yet far from satisfactory. The sciences have not joined hands and made their results coherent, showing nature to be, as it doubtless is, all of one piece. The moral sciences especially are a mass of confusion. Negative, I think, must be the attitude of reason, in the present state of science, upon any hypothesis far outrunning the recorded history and the visible habitat of the human race. Yet exactly the same habits and principles that have secured our present knowledge are still active within us, and promise further discoveries. It is more desirable to clarify our knowledge within these bounds than to extend it beyond them. For while the reward of action is contemplation or, in more modern phrase, experience and consciousness, there is nothing stable or interesting to contemplate except objects relevant to action – the natural world and the mind's ideals.

Both the conditions and the standards of action lie well within the territory which science, after a fashion, already dominates. But there remain unexplored jungles and monster-breeding lairs within our nominal jurisdiction which it is the immediate task of science to clear. The darkest spots are in man himself, in his fitful, irrational disposition. Could a better system prevail in our lives a better order would establish itself in our thinking. It has not been for want of keen senses, or personal genius, or a constant order in the outer world, that mankind have fallen back repeatedly into barbarism and superstition. It has been for want of good character, good example, and good government. There is a pathetic capacity in men to live nobly, if only they would give one another the chance. The ideal of political perfection, vague

and remote as it yet seems, is certainly approachable, for it is as definite and constant as human nature. The knowledge of all relevant truth would be involved in that ideal, and no intellectual dissatisfaction would be felt with a system of ideas that should express and illumine a perfect life.

THE EFFICACY OF THOUGHT

George Santayana. "The Efficacy of Thought." *Journal of Philosophy, Psychology and Scientific Methods* 3.15 (19 July 1906): 410–412.

Professor A. W. Moore, in his courteous review of my book on 'The Life of Reason',[1] has pointed out what he feels to be a discrepancy in my language, and perhaps a difficulty in the subject-matter itself, touching a point of very great importance. This point is the sense in which mental facts may be called influential, may have a function or power.

There are many possible readings of this problem, some of which may be distinguished as follows:

1. It is a function of thought to give an intrinsic value to the moment in which it occurs. Thought has an esthetic or ecstatic quality. This function, inefficacious as it is, would suffice to make thought the most important thing in the world.

2. Thought has the power of asserting ideal verities; it has a contemplative and dialectical function. An ephemeral seraph, alone in the universe, might recite the multiplication table and die. His thought would have possessed two ideal functions, one beatifying, the other self-explicative or discursive.

3. Thought may have a transitive but merely cognitive function; it may represent, and mean to represent, some independent fact, as when I say to myself that Caesar died on the Ides of March. The eventual test of this truth, its consistency with other judgments, its prevalence, its destiny, or its being a thought that would subsist permanently in an organism usefully adapted to a special environment – all this does not enter into the cognitive pretensions of the thought. These are ideal; but as the truth of the thought hangs on the existence of the external fact to which it refers, its truth remains always an assumption from its own point of vantage; though a third person might perhaps have further means of deciding for himself whether that thought had been true or false.

4. Thought may have prophetic scope: it may foretell what is about to take place. This harmony, purely speculative in itself, would, if at all frequent, very much increase the inner wealth and dignity of thought mentioned in 1 and 3.

[1] This *Journal*, Vol. III., No. 8.

5. Mingled with prophecy may be desire; and if to confident prophecy and eager desire an eventual verification accrues, the result is a sense of power. Thought is then supposed to have brought about its own realization, and to be responsible for it. This felt efficacy is always moral, or rather magical. It is a power attributed to thought, in its ideal capacity and by virtue of its intent, to bring about what it calls for, as an incantation or an exorcism might do, through empty reaches of time and space.

6. Thought, taken as a psychological existence, might have a causal influence on a succeeding state of mind, quite apart from the ideal burden of either. Thus, a dialectical argument might bring on a headache or (if mental association were directly efficacious) hearing others speak with a certain accent might cause me to hear myself later speaking with the same, no physical links intervening.

7. Thought might be carried on for a while by dialectical progression, the meaning constituting an evolutionary 'force'. The thought might then be transformed into another irrelevant state of mind, as in 6; but a moment later this state of mind might become a cerebral process, which, in turn, might be propagated for a while mechanically, but might finally evaporate out of the physical world altogether, the 'force' of it going to constitute a fresh mental event, either irrelevant or, by reestablished harmony, cognitive of the physical fact that caused it; and so on as before.

8. Thought might be without efficacy, either in its moral or in its existential capacity; yet the bodily function, the instinct or habit, which it accompanied, might involve the maintenance of that thought, or its dialectical development in time. In this case the thought would be so grounded as to vouch for its occasional reappearance, whenever the juncture reoccurred at which it was evoked originally. Thus books, customs and works of art insure the perpetuity of spiritual experience as, in a larger sense, do the unchanged face of nature and the hereditary structure of animals. Thought might still be called efficacious in the only sense, not magical, in which its efficacy would be at all congruous with its intent; namely, through the natural efficacy of the creature whose life it expressed.

As to my personal opinion in this matter, which I am sorry to see Professor Moore finds ambiguously expounded in my book, it is probably plain enough from the above statement of the various possibilities. 1, 2, 3 and 4 describe purely ideal functions of thought, all of which it undoubtedly reaches at certain moments. 5, on the contrary, describe a superstition; yet it is this superstition, clung to by the unrecognized childishness of man, that alone induces anybody to defend the extravagances and confusions of 6 and 7. People wish thought to be mechanically efficacious because they think it would be a *better guide* than the cerebral process which underlies it; yet why a better guide, unless it operated miraculously, by its intent, and not by virtue of some irrelevant evolution of its substance? 8, accordingly, represents the conclusion

to which I arrive; and it explains certain phrases which I have not studied to avoid, thinking that their metaphorical character would be obvious to the reader. We all speak of Maithus's ideas 'governing' the movement of population, yet hardly expect to be accused of maintaining that poor Maithus's hard thinking caused Israel's fecundity or the congestion in our large cities. A thought is said to govern those portions of existence the movement of which it serves to predict or to describe. One may well say that 'reason is vital impulse modified by reflection'. It is certain that when a man 'reflects' his action changes in consequence, just as he turns aside when he 'sees' an obstacle in front of him; but as his seeing was an impression on his organs, without which his fancy would have pictured nothing, and as his turning was an instinct or habit of his organism, without which the image would have signified no danger; so the pause in reflection was a physical event, accompanied by an oscillation of projects in the mind (for reflection can not decide when reflection shall arise, nor how long it shall last, nor what course it shall take). The consequences of reflection are due to its causes, to the competitive impulses in the body, not to the wistful lucubration itself; for this is mere poetry. People's thoughts are most inadequate and choked just when their action is most rapid and urgent. That consciousness is a lyric cry, even in the midst of business, is something which must be felt, perhaps, to be understood; and they that have feeling, let them feel it.

I may add that the ambiguity which others as well as Professor Moore find in my book seems to come, at least in part, from their generously attributing to it loftier pretensions than it ever puts forth. They begin by reading into my words two doctrines which perhaps they think highly of, namely, that the genesis of knowledge is the genesis of things, and that truth is useful illusion; but they soon find that my expressions contradict these doctrines, which I not only never entertained, but can not even conceive. For in assigning any origin to nature we assume another nature operating behind, while it is hard to see how one illusion could be more useful than another in a vacuum; yet if a determinate environment existed, the true idea of it would be determined by what that environment was, not by the uses which the idea of it might have. What I can readily conceive, however, is how puzzled and disappointed a reader must be who begins by taking for a complete cosmogony what is merely a biography of human reason, and how miserably this whole drama of thought must seem to him to end, if it ends in discovering what has always been true.

RUSSELL'S PHILOSOPHICAL ESSAYS. II. THE CRITIQUE OF PRAGMATISM

George Santayana. "Russell's Philosophical Essays. II. The Critique of Pragmatism." *Journal of Philosophy, Psychology and Scientific Methods* 8.5 (2 March 1911): 113–124.

The time has not yet come when a just and synthetic account of what is called pragmatism can be expected of any man. The movement is still in a nebulous state, a state from which, perhaps, it is never destined to issue. The various tendencies that compose it may soon cease to appear together; each may detach itself and be lost in the earlier system with which it has most affinity. The reader will probably remember Professor Lovejoy's "Thirteen Pragmatisms"; and besides such distinguishable tenets, there are in pragmatism echoes of various popular moral forces, like democracy, impressionism, love of the concrete, respect for success, trust in will and action, and the habit of relying on the future, rather than on the past, to justify one's methods and opinions. Most of these things are characteristically American; and Mr. Russell touches on some of them with more wit than sympathy. Thus he writes: "The influence of democracy in promoting pragmatism is visible in almost every page of William James's writing. There is an impatience of authority, an unwillingness to condemn widespread prejudices, a tendency to decide philosophical questions by putting them to a vote, which contrast curiously with the usual dictatorial tone of philosophic writings.... A thing which simply *is* true, whether you like it or not, is to him as hateful as a Russian autocracy; he feels that he is escaping from a prison, made not by stone walls but by 'hard facts', when he has humanized truth, and made it, like the police force in a democracy, the servant of the people instead of their master. The democratic temper pervades even the religion of the pragmatists; they have the religion they have chosen, and the traditional reverence is changed into satisfaction with their own handiwork. 'The prince of darkness,' James says, 'may be a gentleman, as we are told he is, but whatever the God of earth and heaven is, he can surely be no gentleman.' He is rather, we should say, conceived by pragmatists as an elected president, to whom we give a respect which is really a tribute to the wisdom of our own choice. A government in which we have no voice is repugnant to the democratic temper. William James carries up to heaven the revolt of his New England ancestors:

the Power to which we can yield respect must be a George Washington rather than a George III."

Many emotional impulses of this sort might be discovered in pragmatism; and yet what seems to be, at this moment, the dominant note, among those who have most felt the influence of the movement, is what is called the New Realism; and to something very like this, under the name of Radical Empiricism, Professor James himself seemed to turn in the end as to a haven after the storm. But this new realism is not a doctrine resting at all on vague moral aspirations. It is nothing if not positive, scientific, and (most unlike the earlier pragmatism) even materialistic and mathematical. What it chiefly inherits from pragmatism, however, is the determination to reduce ideal relations, such as that of knowing, to natural relations between dynamic processes. That such dynamic natural relations underlie knowing and all spiritual activity was surely the guiding insight of pragmatism, on its technical side; while the habit, most unfortunate, as it seems to me, of actually identifying these natural relations with the ideal ones in which they find conscious expression, has been the source of infinite confusion, both to pragmatists and to their opponents, and the ground of that decided rejection which the new doctrine has met with in almost every quarter.

It is not, however, in any general picture of pragmatism that Mr. Russell might draw that the value of his criticism would be likely to lie. He attempts no such picture; and his exact and spare way of philosophizing would hardly be suited to the task. That would require a delicate blending of historical perspectives and some faith in blundering, kindly, brave human nature. What Mr. Russell catches and dwells upon are certain high lights of pragmatic theory; and however inadequately these precise points, even when added together, may represent the movement, they are of interest in themselves, and what our critic has to say on them is keen and cogent and, to my mind, altogether final.

A point of fundamental importance, about which pragmatists have been far from clear, and perhaps not in agreement with one another, is the sense in which their psychology is to be taken. "The facts that fill the imaginations of pragmatists," Mr. Russell writes (p. 104), "are psychical facts; where others might think of the starry heavens, pragmatists think of the perception of the starry heavens; where others think of God, pragmatists think of the belief in God, and so on. In discussing the sciences, they never think, like scientific specialists, about the facts upon which scientific theories are based; they think about the theories themselves. Thus their initial question and their habitual imaginative background are both psychological." This is so true that unless we make the substitution into psychic terms instinctively, the whole pragmatic view of things will seem paradoxical, if not actually unthinkable. For instance, pragmatists might protest against the accusation that "they never think about the facts upon which scientific theories are based," for they lay

a great emphasis on facts. Facts are the cash which the credit of theories hangs upon. Yet, this protest, though sincere, would be inconclusive, and in the end it would illustrate Mr. Russell's observation, rather than refute it. For we should presently learn that these facts can be made by thinking, that our faith in them may contribute to their reality, and may modify their nature; in other words, these facts are our immediate apprehensions of fact, which it is indeed conceivable that our temperaments, expectations, and opinions should modify. Thus the pragmatist's reliance on facts does not carry him beyond the psychic sphere; his facts are only his personal experiences. Personal experiences may well be the basis for no less personal myths; but the effort of intelligence and of science is rather to find the basis of the personal experiences themselves; and this non-psychic basis of experience is what common sense calls the facts, and what practice is concerned with. Yet these are not the *pragmata* of the pragmatist, for it is only the despicable intellectualist that can arrive at them; and the bed-rock of facts that the pragmatist builds upon is avowedly drifting sand. Hence the odd expressions, new to literature and even to grammar, which bubble up continually in pragmatist writings. "For illustration take the former fact that the earth is flat,"[1] says one, quite innocently; and another observes that "two centuries later, nominalism was evidently true, because it alone would legitimize the local independence of cities."[2] Lest we should suppose that the historical sequence of these "truths" or illusions is, at least, fixed and irreversible, we are soon informed that the past is always changing, too; that is (if I may rationalize this mystical dictum), that history is always being rewritten, and that the growing present adds new relations to the past, which lead us to conceive or to describe it in some new fashion. Even if the ultimate inference is not drawn, and we are not told that this changing idea of the past is the only past that exists – the real past being unattainable and therefore, for personal idealism, non-existent – it is abundantly clear that the effort to distinguish fact from theory can not be successful, so long as the psychological way of thinking prevails; for a theory, psychologically considered, is a bare fact in the experience of the theorist, and the other facts of his experience are so many other momentary views, so many scant theories, to be immediately superseded by other "truths in the plural." Sensations and ideas are really distinguishable only by reference to what is assumed to lie without; of which external reality experience is always an effect (and in that capacity is called sensation) and often at the same time an apprehension (and in that capacity is called idea).

It is a crucial question, then, in the interpretation of pragmatism, whether the psychological point of view, undoubtedly prevalent in that school, is the

[1] "Studies in Logical Theory," edited by John Dewey, p. 106.

[2] This *Journal*, Vol. IV., No. 24, p. 661.

only or the ultimate point of view which it admits. The habit of studying ideas rather than their objects might be simply a matter of emphasis or predilection. It might merely indicate a special interest in the life of reason, and be an effort, legitimate under any system of philosophy, to recount the stages by which human thought, developing in the bosom of nature, may have reached its present degree of articulation. I myself, for instance, like to look at things from this angle: not that I have ever doubted the reality of the natural world, or been able to take very seriously any philosophy that denied it, but precisely because, when we take the natural world for granted, it becomes a possible and enlightening inquiry to ask how the human animal has come to discover his real environment, in so far as he has done so, and what dreams have intervened or supervened in the course of his rational awakening. To the habit of studying in this way the tragi-comedy of cognitive experience, I probably owe the generous appreciation, somewhat disconcerting at times, with which some pragmatists have honored me, as well as the contempt or distrust my writings seem to inspire in other critics, who think me a confused babbler and a romanticist, because indeed I am more interested in the general imaginative life of mankind than in the few shreds of it that these same critics cherish as dogmas; for if they believed simply, as I do, in the natural world, they would not have misunderstood my intention. On the other hand, a psychological point of view might be equivalent to the idealistic doctrine that the articulation of human thought constitutes the only structure of the universe, and its whole history. This may be the position of Mr. Schiller, but hardly that of the other leaders of the pragmatist school. I remember Professor Dewey saying in conversation that he did not doubt that the mind of a friend of ours, *M*, existed independently of our ideas of *M*'s mind; but it was not for philosophy to discuss that independent being; the business of philosophy was merely to fix the logic and system of our own knowledge. According to this view, pragmatism would seem to be a revised version of the transcendental logic, leaving logic still transcendental, that is, still concerned with the evolution of the categories. The revision would consist chiefly in this, that empirical verification, utility, and survival would take the place of dialectical irony as the force governing the evolution. It would still remain possible for other methods of approach than this transcendental pragmatism, for instinct, perhaps, or for revelation, to bring us into contact with things-in-themselves. A junction might thus be effected with the system of M. Bergson, which would lead to this curious result: that pragmatic logic would be the method of intelligence, because intelligence is merely a method, useful in practice, for the symbolic and improper representation of reality; while another non-pragmatic method – sympathy and dream – would alone be able to put us in possession of direct knowledge and genuine truth. So that, after all, the pragmatic "truth" of working ideas would turn out to be what it has seemed hitherto to mankind, namely, no real truth, but rather a convenient sort of fiction,

which ceases to deceive when once its merely pragmatic value is discounted by criticism.

I remember, too, once putting a question on this subject to Professor James also; and his answer was one which I am glad to be able to record. In relation to his having said that "as far as the past facts go, there is no difference, ... be the atoms or be the God their cause,"[3] I asked whether, if God had been the cause, apart from the value of the idea of him in our calculations, his existence would not have made a difference to *him*, as he would be presumably self-conscious. "Of course," said Professor James, "but I wasn't considering that side of the matter; I was thinking of our idea." The choice of the subjective point of view, then, was deliberate here, and frankly arbitrary; it was not intended to exclude the possibility or legitimacy of the objective attitude. And the original reason for deliberately ignoring, in this way, the realistic way of thinking, even while admitting (like Professor Dewey) that it represents the real state of affairs, would have been, I suppose, that what could be verified was always some further effect of the real objects, and never those real objects themselves; so that for interpreting and predicting our personal experience on1y the hypothesis of objects was pertinent, while the objects themselves, except as so represented, were useless and unattainable. The case, if I may adapt a comparison of Mr. Russell's, was as if we possessed a catalogue of the library at Alexandria, all the books being lost forever; it would be only in the catalogue that we could practically verify their existence or character, though doubtless, by some idle flight of imagination, we might continue to think of the books, as well as of those titles in the catalogue which alone could appear to us in experience. Pragmatism, approached from this side, would then seem to express an acute critical conscience, a sort of will not to believe; not to believe, I mean, more than is absolutely necessary for solipsistic practice.

Such economical faith, enabling one to dissolve the hard materialistic world into a work of mind, which mind might outflank, was traditional in the radical Emersonian circles in which pragmatism sprang up. It is one of the approaches to the movement; yet we may safely regard the ancestral transcendentalism of the pragmatists as something which they have turned their back upon, and mean to disown. It is destined to play no part in the ultimate result of pragmatism. This ultimate result promises to be, on the contrary, a direct and materialistic sort of realism. This alone is congruous with the scientific affinities of the school and its young American temper. Nor is the transformation very hard to effect. The world of solipsistic practice, if you remove the romantic self that was supposed to evoke it, becomes at once the sensible world; and the problem is only to find a place in the mosaic of objects of sensation for those cognitive and moral functions which the soul was once

[3] "Pragmatism," p. 101.

supposed to exercise in the presence of an independent reality. But this problem is precisely the one that pragmatists boast they have already solved; for they have declared that consciousness does not exist, and that objects of sensation (which at first were called feelings, experiences, or "truths") know or mean one another when they lead to one another, when they are poles, so to speak, in the same vital circuit. The spiritual act which was supposed to take things for its object is to be turned into "objective spirit," that is, into dynamic relations between things. Rather than admit that the mind of *M* exists, but is beyond the reach of philosophy, this post-pragmatic theory will identify the mind of *M* with a material system consisting of *M*'s body and such surrounding objects as *M*'s body is reacting upon. The philosopher will deny that he has any other sort of mind himself, lest he should be shut up in it again, like a sceptical and disconsolate child; while if there threatens to be any covert or superfluous reality in the self-consciousness of God, nothing will be easier than to deny that God is self-conscious; for indeed, if there is no consciousness on earth, why should we imagine that there is any in heaven? The psychologism with which the pragmatists started seems to be passing in this way, in the very effort to formulate it pragmatically, into something which, whatever it may be, is certainly not psychologism. But the bewildered public may well ask whether it is pragmatism either.

There is another crucial point in pragmatism which the defenders of the system are apt to pass over lightly, but which Mr. Russell regards (justly, I think) as of decisive importance. Is, namely, the pragmatic account of truth intended to cover all knowledge, or one kind of knowledge only? Apparently the most authoritative pragmatists admit that it covers one kind only; for there are two sorts of self-evidence in which, they say, it is not concerned: first, the dialectical relation between essences; and second, the known occurrence or experience of facts. There are obvious reasons why these two kinds of cognitions, so interesting to Mr. Russell, are not felt by pragmatists to constitute exceptions worth considering. Dialectical relations, they will say, are verbal only; that is, they define ideal objects, and certainty in these cases does not coerce existence, or touch contingent fact at all. On the other hand, such apprehension as seizes on some matter of fact, as for instance, "I feel pain," or "I expected to feel this pain, and it is now verifying my expectation," though often true propositions, are not *theoretical* truths; they are not, it is supposed, questionable beliefs but rather immediate observations. Many of these apprehensions of fact (or all, perhaps, if we examine them scrupulously) involve the veracity of memory, surely a highly questionable sort of truth; and, moreover, verification, the pragmatic test of truth, would be obviously impossible to apply, if the prophecy supposed to be verified were not assumed to be truly remembered. How shall we know that our expectation is fulfilled, if we do not know directly that we had such an expectation? But if we know our past experience directly – not merely knew it when present, but know now

what it was, and how it has led down to the present – this amounts to enough knowledge to make up a tolerable system of the universe, without invoking pragmatic verification or "truth" at all. I have never been able to discover whether, by that perception of fact which is not "truth" but fact itself, pragmatists meant each human apprehension taken singly, or the whole series of these apprehensions. In the latter case, as in the philosophy of M. Bergson, all past reality might constantly lie open to retentive intuition, a form of knowledge soaring quite over the head of any pragmatic method or pragmatic "truth." It looks, indeed, as if the history of at least personal experience were commonly taken for granted by pragmatists, as a basis on which to rear their method. Their readiness to make so capital an assumption is a part of their heritage from romantic idealism. To the romantic idealist science and theology are tales which ought to be reduced to an empirical equivalent in his personal experience; but the tale of his personal experience itself is a sacred figment, the one precious conviction of the romantic heart, which it would be heartless to question. Yet here is a kind of assumed truth which can not be reduced to its pragmatic meaning, because it must be true literally in order that the pragmatic meaning of other beliefs may be conceived or tested at all.

Now, if it be admitted that the pragmatic theory of truth does not touch our knowledge either of matters of fact or of the necessary implications of ideas, the question arises: What sort of knowledge remains for pragmatic theory to apply to? Simply, Mr. Russell answers, those "working hypotheses" to which "prudent people give only a low degree of belief" (p. 147). For "we hold different beliefs with very different degrees of conviction. Some – such as the belief that I am sitting in a chair, or that 2 + 2= 4 – can be doubted by few except those who have had a long training in philosophy. Such beliefs are held so firmly that non-philosophers who deny them are put into lunatic asylums. Other beliefs, such as the facts of history, are held rather less firmly.... Beliefs about the future, as that the sun will rise to-morrow and that the trains will run approximately as in Bradshaw, may be held with almost as great conviction as beliefs about the past. Scientific laws are generally believed less firmly.... Philosophical beliefs, finally, will, with most people, take a still lower place, since the opposite beliefs of others can hardly fail to induce doubt. Belief, therefore, is a matter of degree. To speak of belief, disbelief, doubt, and suspense of judgment as the only possibilities is as if, from the writing on the thermometer, we were to suppose that blood heat, summer heat, temperate, and freezing were the only temperatures" (p. 145). Beliefs which require to be confirmed by future experience, or which actually refer to it, are evidently only presumptions; it is merely the truth of presumptions that empirical logic applies to, and only so long as they remain presumptions. Presumptions may be held with very different degrees of assurance, and yet be acted upon, in the absence of any strong counter-suggestion; as the confi-

dence of lovers or of religious enthusiasts may be at blood heat at one moment and freezing at the next, without a change in anything save in the will to believe. The truth of such presumptions, whatever may be the ground of them, depends in fact on whether they are to lead (or, rather, whether the general course of events is to lead) to the further things presumed; for these things are what the presumptions refer to explicitly.

It sometimes happens, however, that presumptions (being based on voluminous blind instinct rather than on distinct repeated observations) are expressed in consciousness by some symbol or myth, as when a man says he believes in his luck; the presumption really regards particular future chances and throws of the dice, but the emotional and verbal mist in which the presumption is wrapped, veils the pragmatic burden of it; and a metaphysical entity arises, called luck, in which a man may think he believes rather than in a particular career that may be awaiting him. Now since this entity, luck, is a mere word, confidence in it, to be justified at all, must be transferred to the concrete facts it stands for. Faith in one's luck must be pragmatic, but simply because faith in such an entity is not needful nor philosophical at all. The case is the same with working hypotheses, when that is all they are; for on this point there is some confusion. Whether an idea is a working hypothesis merely or an anticipation of matters open to eventual inspection may not always be clear. Thus the atomic theory, in the sense in which most philosophers entertain it to-day, seems to be a working hypothesis only; for they do not seriously believe that there are atoms, but in their ignorance of the precise composition of matter, they find it convenient to speak of it as if it were composed of indestructible particles. But for Democritus and for many modern men of science the atomic theory is not a working hypothesis merely; they do not regard it as a provisional makeshift; they regard it as a probable, if not a certain, anticipation of what inspection would discover to be the fact, could inspection be carried so far; in other words, they believe the atomic theory is true. If they are right, the validity of this theory would not be that of pragmatic "truth" but of pragmatic "fact"; for it would be a view, such as memory or intuition or sensation might give us, of experienced objects in their experienced relations; it would be the communication to us, in a momentary dream, of what would be the experience of a universal observer. It would be knowledge of reality in M. Bergson's sense. Pragmatic "truth," on the contrary, is the relative and provisional justification of fiction; and pragmatism is not a theory of truth at all, but a theory of theory, when theory is instrumental. For theory has more than one signification. It may mean such a symbolic or foreshortened view, such a working hypothesis, as true and full knowledge might supersede; or it may mean this true and full knowledge itself, a synthetic survey of objects of experience in their experimental character. Algebra and language are theoretical in the first sense, as when a man believes in his luck; historical and scientific imagination are theoretical in the second

sense, when they gather objects of experience together without distorting them. But it is only to the first sort of theory that pragmatism can be reasonably applied; to apply it also to the second would be to retire into that extreme subjectivism which the leading pragmatists have so hotly disclaimed. We find, accordingly, that it is only when a theory is avowedly unreal, and does not ask to be believed, that the value of it is pragmatic; since in that case belief passes consciously from the symbols used to the eventual facts in which the symbolism terminates, and for which it stands.

It may seem strange that a definition of truth should have been based on the consideration of those ideas exclusively for which truth is not claimed by any critical person, such ideas, namely, as religious myths or the graphic and verbal machinery of science. Yet the fact is patent, and if we considered the matter historically it might not prove inexplicable. Theology has long applied the name truth preeminently to fiction. When the conviction first dawned upon pragmatists that there was no absolute or eternal truth, what they evidently were thinking of was that it is folly, in this changing world, to pledge oneself to any final and inflexible creed. The pursuit of truth, since nothing better was possible, was to be accepted instead of the possession of it. But it is characteristic of Protestantism that, when it gives up anything, it transfers to what remains the unction, and often the name, proper to what it has abandoned. So, if truth was no longer to be claimed or even hoped for, the value and the name of truth could be instinctively transferred to what was to take its place – spontaneous, honest, variable conviction. And the sanctions of this conviction were to be looked for, not in the objective reality, since it was an idle illusion to fancy we could get at that, but in the growth of this conviction itself, and in the prosperous adventure of the whole soul, so courageous in its self-trust, and so modest in its dogmas. Science, too, has often been identified, not with the knowledge men of science possess, but with the language they use. If science meant knowledge, the science of Darwin, for instance, would lie in his observations of plants and animals, and in his thoughts about the probable ancestors of the human race – all knowledge of actual or possible facts. It would not be knowledge of "selection" or of "spontaneous variation," terms which are mere verbal bridges over the gaps in that knowledge, and mark the *lacunae* and unsolved problems of the science. Yet it is just such terms that seem to clothe "Science" in its pontifical garb; the cowl is taken for the monk; and when a penetrating critic, like M. Henri Poincaré, turns his subtle irony upon them, the public cries that he has announced the "bankruptcy of science," whereas it is merely the language of science that he has reduced to its pragmatic value – to convenience and economy in the registering of facts – and has by no means questioned that positive and cumulative knowledge of facts which science is attaining. It is an incident in the same general confusion that a critical epistemology, like pragmatism, analyzing these figments of scientific or theological theory,

should innocently suppose that it was analyzing "truth"; while the only view to which it really attributes truth is its view of the system of facts open to possible experience, a system which those figments presuppose and which they may help us in part to supply, where it is accidentally hidden from human inspection.

Mr. Russell, with the candor and courage that distinguish him, has not wished to aim these and similar cruel shafts at the pragmatist without exposing himself in turn to attack, and his book closes with a brief but complicated essay "On the Nature of Truth." In asserting the truth or falsity of any opinion, it is assumed that the force of the predicates "true" and "false" is perfectly well known; but what *is* the force of these predicates? Mr. Russell begins his reply by agreeing with Professor James on the point that truth should be predicated of beliefs, not of things. "When, for example, we see the sun shining, the sun itself is not 'true', but the judgment 'the sun is shining' is true" (p. 172). Thus "it is plain that there can be no truth or falsehood unless there are minds to judge. Nevertheless it is plain, also, that the truth or falsehood of a given judgment depends in no way upon the person judging, but solely upon the facts about which he judges." Were there no false judgments it would be plausible, Mr. Russell thinks, to assume a true "objective," that is, an objective truth, which the true judgment asserts; but it is not possible to admit false "objectives" to match, and, as false judgments assert something, the theory of true "objectives" for truths must be abandoned. Instead we may postulate a number of objective terms, standing in some objective relation to one another; and a true judgment will be one that assigns to those several terms the relation in which they actually stand. "Every judgment is a relation of a mind to several objects, one of which is a relation; the judgment is true when the relation which is one of the objects relates the other objects, otherwise it is false" (p. 181). And we learn subsequently that this relation must not be conceived too abstractly, so as to be reversible; it may hold in one direction only, and that direction must, in that case, be specified in the true judgment.

I confess to some surprise that Mr. Russell should admit that there can be no truth unless there are minds. When one holds that ideal essences and facts and the relations between them are all independent of the judging mind, it seems unnatural to assert that this existing standard for true judgments is not itself the truth. Of course truth is not synonymous with reality; but "the truth," as I apprehend the force of that phrase, means the form of reality, or the complex of all those possible judgments which the reality justifies. This complex of possible true judgments would be determined by the reality whether any one ever pronounced any of those judgments or not; so that it would be, at the very most, possible minds, and not actual minds, that would be involved in the being of truth. Nor does the difficulty about "objectives" for error, which Mr. Russell puts forward, seem to me very serious. The

content, or the esthetic essence, envisaged in a false judgment is one thing, and the external object, or the complex of necessary relations, in which that essence is alleged to lie, is quite another. The form of reality is the standard for errors as well as for truths; if error did not mean to describe reality it would not be error, but mere imagination. The "objective" which a false judgment requires, so that it may assert something, is its own content or esthetic essence; the "objective" which it requires, so that it may be true or false, is the truth outside. I may not have fully understood Mr. Russell's argument, which is very concise; but the conclusion, at which he arrives, that false judgments must have complex objects, seems certain on other grounds. If reality had no multiplicity we should either have to apprehend it truly or not to refer to it at all. What exposes us to err is that we may conceive one element of reality, fixing upon it by some sign that determines it sufficiently, and then combine with it other elements which are not conjoined with it in fact.

Perhaps some of the difficulties which meet Mr. Russell here may be due to another tenet of his, which itself seems very questionable, namely, that perception, as distinguished from judgments based upon it, is infallible. If we subtract the accompanying judgments from perception, however, what remains would not appear to be still a judgment; it would be merely an essence presented; and why need the sense-datum, or esthetic essence, which perception presents, have any further embodiment in the universe? Doubtless, there are no perceptions without a material cause, as there can be none without an esthetic essence; but it is a long way round – the whole long circuit of human disillusion and science – from the first esthetic essence, perceived in a dream, to the ultimate knowledge of what may have been its cosmic causes. Professor James used to exclaim, when he was startled by some fresh and unlooked-for misunderstanding, that you could say nothing safely in philosophy unless you said everything; and I suspect that these obscure points in Mr. Russell's doctrine will be made clearer when he has given us his views on the material world, and on psychology; for there are hints in his writings, and in Mr. Moore's, of a new realism with an atomic migratory soul, genuine matter, and secondary qualities subsisting independently in objects; a system which promises to be no less interesting than the new realism already launched in America, and possibly more complete.

BELIEF IN EXPERIENCE

George Santayana. "Belief in Experience." *Scepticism and Animal Faith* (New York: Charles Scribner's Sons, 1923), chap. 15, pp. 134–144.

I have now agreed to believe that discourse is a contingent survey of essence, partial, recurrent, and personal, with an arbitrary starting-point and an arbitrary direction of progress. It picks up this essence or that for no reason that it can assign. However dialectical the structure of the theme considered may be, so that its various parts seem to imply one another, the fact that this theme rather than any other is being considered is a brute fact: and my discourse as a whole is a sheer accident, initiated, if initiated at all, by some ambushed power, not only in its existence, but in its duration, direction, and scope.

Nevertheless this fatality does not raise any problem in that discourse itself, because it occasions no surprise. Problems are created after discourse is in full swing, by contradictory presumptions or aching voids arising within it. There are no problems in nature, and none in the realm of essence. Existence – the most inexplicable of surds – is itself no problem in its own eyes: it takes itself blandly for granted, so long as it is prosperous. This is a healthy dullness on its part, because if there is no reason why a particular fact should exist rather than any other, or none at all, there is also no reason why it should not exist. The philosopher who has learned to make nature the standard of naturalness will not wonder at it. He will repeat on a large scale that act of ready submission to fate which every new-born intuition performs spontaneously. It does not protest against its sudden existence. It is not surprised at the undeserved favour that has fallen to its share. It modestly and wisely forgets itself and notes only the obvious, profoundly self-justified essence which appears before it. That this essence might just as well, or might far better, have been replaced by some other is not a suggestion to be possibly gathered from that essence itself. Nor is the psyche (the ambushed power from which the intuition actually comes) less self-satisfied and at peace. The psyche, too, takes her own idiosyncrasy for granted, singular and highly determinate as this is, and extraordinarily censorious concerning all other things. Her nature seems to her by right everlasting, and that to which it is the obvious duty of all other things to adjust themselves. God, too, if we refer these agreeable fatalities ultimately to his decrees, is conceived in like manner never to wonder why he exists although evidently nothing could have previ-

ously demanded his existence, or prepared the way for it, or made it intelligible. Nevertheless the mortal psyche perhaps thinks she sees the secret even of that, because it was necessary that God should exist in order to make her own existence perfectly safe, legitimate, and happy for ever. This assurance is needed, because there are unfortunately some circumstances that might suggest the opposite.

Before turning to these circumstances, it may be well to observe that actual discourse, as distinguished from the internal dialectic of essences, may have any degree of looseness; that is, the terms which it takes up in succession may have nothing to do with one another essentially. There is no added paradox in this: what is groundless and irrational in its inception may well be groundless and irrational in its procedure, and an appearance that has no reason for arising has no reason for not yielding to any other appearance, or to vacancy. And yet sometimes the course of appearances does produce wonder and discontent. How can this be? If I am not surprised at beginning to exist, or at finding something before me, since present being cannot contain any presumption or contradiction against itself, so it would seem that I should not be surprised at any changes in existence, however radical and complete. Often, indeed, I am not surprised, but follow the development of discourse, as in a dream, with perfect acquiescence, or even with a distinct premonition of what is coming, and eagerness that it should come. If I were a pure spirit, or even an open mind, this ought to be always the case. However different essences may be, they cannot in their own realm exclude or contradict one another; there, infinite diversity provokes no conflict and imposes no alternatives, and the being of anything, far from impeding that of other things, seems positively to invite and to require it, somewhat as every part of Euclidean space, far from denying the other parts, implies them. Irrelevance is, as it were, mere distance; and there is nothing strange or evil in quickness of thought, that should jump from one essence to another altogether dissimilar to it, or even contrary.

And yet I cannot prolong or intensify discourse without soon coming upon what I call interruption, confusion, doubt, or contradiction. An impulse to select, to pursue, and to reject specific essences insinuates itself into discourse. Why this animosity or this impatience? I do not disparage, nor subordinate, nor remove the circle from the realm of essence, when I think of the square and say it is no circle. Why then should I be angry if I find the one rather than the other? Evidently my discourse here is not pure contemplation. Of course, no essence is any other essence; but a clear spirit would not call any two essences incompatible. Their diversity is part of their being; they *are* because, each being eternally itself, the two are eternally different. If they are incompatible, I must ask: Incompatible for what purpose? Even in calling them contradictory, I am surreptitiously speaking for some hidden interest, which cannot put up with them both. There is an inertia or prior direction

somewhere, in the region of what I call myself, that demands one of them, and rejects the other for the innocent crime of not being that one. The incongruous essence appearing offends me because I am wedded to an old one, and to its close relations. I will tolerate nothing but what I meant should come, what fills my niche, and falls in with my undertaking.

Irrelevance, incongruity, and contradiction are accordingly possible in discourse only because discourse is not a play of essences but a play of attention upon them; which attention is no impartial exercise of spirit but a manifestation of interest, intent, preference, and preoccupation. A hidden life is at work. If I deny this, because my skepticism eschews everything hidden, I must consistently abandon all dialectic and revert to undirected dreaming, without comments on my dream intended to be veridical: because if the least comment on my dreams were veridical I must begin at once to reject, in my comments, all the essences suggesting themselves which deviate from that particular dream I mean to describe. Meaning, which is my guide in discriminating one suggestion from another as being the right one, springs from beneath the surface; it is a nether influence. It is a witness to my psychic life going on beneath, which can be disturbed by the intrusion of one event, or furthered by another; and this subterranean impulse breaks out into judgments about the rightness and wrongness of essences – utterly absurd and unmeaning judgments if the essences were considered simply in themselves. If I feel that they clash, if I make a stumbling-block of their irrelevance or diversity, I prove that I am discoursing about them for an ulterior purpose, in the service of some alien interest. I am stringing my pearls; therefore I require them to be of a particular quality. I am a collector, not a poet; and what concerns me, even in the purest dialectic or the most desultory dream, is not to explore essence, but to gather *experience*. The psyche below is busy selecting her food, fortifying her cave, and discriminating her friends from her enemies; and in these meanderings of mine over the realm of essence, in spite of myself, I am only her scout.

By experience I understand a fund of wisdom gathered by living. I call it a fund of wisdom, rather than merely memora or discursive ideation, because experience accrues precisely when discrimination amongst given essences is keenest, when only the relevant is retained or perhaps noticed, and when the psyche sagaciously interprets data as omens favorable or unfavorable to her interests, as perilous or inviting, and, if she goes wrong, allows the event to correct her interpretation. I think it mere mockery to use the word experience for what is not learning or gathering knowledge of facts; if experience taught me nothing it would not be experience, but reverie. Experience accordingly presupposes intent and intelligence, and it also implies, as will appear presently, a natural world in which it is possible to learn to live better by practicing the arts.

Intuition is an event, although it reveals only an essence; and in like manner discourse is an experience, even when its deliverance is mere dialectic. It is an

experience for two reasons: first, because it is guided unawares by the efforts of the psyche to explore, not the realm of essence, but the world that controls her fortunes, and secondly, because the essences unrolled before it, apparently at random and for no reason, really convey knowledge, in reality they are manifestations to the psyche of that surrounding world which it concerns her to react upon wisely. Discourse is hers; and it is full of the names – since images not auditory may be names also – which she gives to her friends and enemies, and of her ingenious imaginations concerning their ways. However original the terms of discourse may be, under the control of the psyche and her environment they fall into certain rhythms; they run into familiar sequences; they become virtual and available knowledge of things, persons, nature, and the gods. Imagination would be very insecure and inconstant in these constructions, and they would not become automatic habits in discourse, if instinct within and nature without did not control the process of discourse, and dictate its occasions. So controlled, discourse becomes experience.

That discourse is secretly an experience, and may be turned into knowledge, becomes particularly evident when it is interrupted by *shocks*. Not only may an essence suddenly present itself which was not the essence I expected or should have welcomed, but the whole placid tenor of my thoughts may be arrested or overwhelmed. I may suffer a sort of momentary and conscious death, in that I survive to feel the extinction of all that made up my universe, and to face a blank, or a precipice. When in my placid discourse one thing seemed to contradict another, they were but rival images in the same field, and I had but to choose between them, and proceed with the argument. Shock contradicts nothing, but uproots the whole experience. The lights go out on the stage, and discourse loses its momentum.

In the sense of contradiction there is probably some element of shock. The purest aesthetic or logical contemplation hardly goes on without a throbbing accompaniment of interest, haste, reversals, and satisfactions; but these dramatic notes are merged in the counterpoint of the themes surveyed, and I think, prove, and enjoy without noticing that I do so. But when a clap of thunder deafens me, or a flash of lightning at once dazzles and blinds me, the fact that something has *happened* is far more obvious to me than just what it is that has occurred; and there are perhaps shocks internal to the psyche in which the tension of the event reaches a maximum, whilst the nature of it remains so obscure that perhaps my only sense of it is a question, a gasp, or a recoil. The feeling present in such a case is, with but little further qualification, the sheer feeling of experience.

Now experience of the most brutal and dumbest sort may be theoretically described, and described exhaustively, in terms of the successive intuition of essences; for loudness, dazzlingness, pain, or terror are essences or elements of essences like any other data; and when such essences are present, all is present that it is possible ever to feel in that direction, and with any degree

of intensity. Utter blankness, intolerable strain, shrieking despair, is just the essences they are, and they are unrolled and revealed to intuition like any other essences. But such intuitions, being those proper to the most brutal and rudimentary life, have a suasion in them out of all proportion to their articulation, or rather, we might almost say, inversely proportional to it; as if the more an experience meant the less it cried out, and the more it cried out the less it meant. The purest discourse is (without noticing it) an experience and the blindest experience (also without noticing it) is a discourse, since we should not call it experience if it contained no sense of passage, no experiential perspective; but in proportion as shock cancels discourse and obliterates its own background, experience becomes mere experience, and inarticulate.

In brute experience, or shock, I have not only a clear indication, for my ulterior reflection, that I exist, but a most imperious summons at that very moment to *believe* in my existence. Discourse, as I first disentangled the evidence for it from the pure intuition of essence, seemed to be a progressive observation of the permanent – studious attention perusing and registering the essential mutual relations of given terms. But now, when shock interrupts me, discourse suffers violence. The subject-matter itself takes up arms; one object leaves me in the lurch, while another, quite irrelevantly, assaults me. And since my discourse witnesses and records this revolution, I must now assert it to be a permanent knowledge of the changing.

Shocks *come*: if they did not *come*, if I had not pre-existed, if I had never been anything more than the intuition of this shock, then this shock would not be a shock in fact, but only the illusion of a shock, only the essence of shock speciously persuading me that something had happened, when in fact nothing had occurred. If the sense of shock does not deceive me, I must have passed from a state in which the shock was not yet, into the state in which the shock first startled me; and I must since have passed from that startled state into another, in which my intuition covers synthetically the coming, the nature, and the subsidence of that shock; so that I am aware how startled I was, without being startled afresh now. A wonderful and ambiguous presence of the absent and persistence of the receding, which is called *memory*. My objects have receded, yet I continue to consider them. They are no longer essences, but facts, and my consideration is not intuition of something given but faith in something absent, and a persistent indication of it as still the same object, although my image of it is constantly changing, is perhaps intermittent, and probably grows fainter, vaguer, and more erroneous at every instant.

Experience of shock, if not utterly delusive, accordingly establishes the validity of memory and of transitive knowledge. It establishes realism. If it be true that I have ever had any experience, I must not only have existed unawares in order to gather it, but I am justified in explicitly asserting a whole realm of existence, in which one event may contain realistic knowledge of

another. Experience, even conceived most critically as a series of shocks overtaking one another and retained in memory, involves a world of independent existences deployed in an existing medium. Belief in experience is belief in nature, however vaguely nature may as yet be conceived, and every empiricist is a naturalist in principle, however hesitant his naturalism may be in practice.

Nevertheless shock, like any other datum, intrinsically presents an essence only, and *might* be nothing more; but in that case the dogmatic suasion of it (which alone lends interest to so blank an experience) would be an illusion. The intuition would be what it is, but it would be nobody's intuition, and it would mean nothing. For I should not be a self, if that intuition made up my whole being, so that it involved no change in my condition, but was perhaps itself the whole universe. Shock will not suffer me, while it lasts, to entertain any such hypothesis. It is itself the most positive, if the blindest, of beliefs; it loudly proclaims an event; so that if by chance the change which I feel were merely a feeling within the unity of apperception, shock would be an illusion, in the only sense in which this can be said of any intuition: it would incite me to a false belief that something like the given essence existed. If the change has really occurred, and not merely been imagined, shock is not only intuition of change, but trouble in a process of change enveloping that intuition. I am right in positing a desultory experience in which this intuition is an incident. I am not a spectator watching this cataract, but a part of the water precipitated over the edge. Thus if being shocked was, as perhaps it ought to be, the first sensation in life, it proclaimed the existence of a previous state without sensation. Unless it is an illusion, which I cannot admit while I feel it, it implies variation in a voluminous vegetative life in which the sense of surprise is a true indication of novelty.

Before I had noticed shock, or consented to accept its witness, I had already admitted, on dialectical grounds, that discourse was a process; but now that I observe how shocks, more or less violent, interrupt discourse at every moment, I can call discourse experience. For now I see that in endeavoring to trace dialectical relations discourse is not itself dialectical. Sheer chance decides whether it shall pursue faithfully the theme it may have picked out, as sheer chance decided that it should pick up that theme in particular. In my theoretical bewilderment and helplessness before this absolute contingency of all themes and all data, I am steadied only by animal presumptions, habits, expectations, or omens, all of which my skeptical reflection must condemn as utterly arbitrary. I can only say that I am the sport of an unfathomable destiny; that in these shocks that fall upon me thick and fast, and in the calmer stretches between them, miscellaneous essences are revealed to me, most of them gratuitous and mutually irrelevant; and that if the current of them did not carry me, somewhat congenially, into a vortex of work and play, I should be condemned for ever to blank watching and to sheer wonder. The very belief

in experience is a suggestion of instinct, not of experience itself. The steadfastness of my nature, doggedly retaining its prejudices and assuming its power, supplies and imposes a routine upon my experience which is far from existing in my direct intuitions, very shifty in their quality (even when signs of the same external object) and much mixed with dream. Even the naturalist has to make up by analogy and presumption (which perhaps he calls induction) the enormous spaces between and beyond his actual observations.

Belief in experience is the beginning of that bold instinctive art, more plastic than the instinct of most animals, by which man has raised himself to his earthly eminence: it opens the gates of nature to him, both within him and without, and enables him to transmute his apprehension, at first merely aesthetic, into mathematical science. This is so great a step that most minds cannot take it. They stumble, and remain entangled in poetry and in gnomic wisdom. Science and reasonable virtue, which plunge their roots in the soil of nature, are to this day only partially welcome or understood. Although they bring freedom in the end, the approach to them seems sacrificial, and many prefer to live in the glamour of intuition, not having the courage to believe in experience.

DEWEY'S NATURALISTIC METAPHYSICS

George Santayana. "Dewey's Naturalistic Metaphysics." *Journal of Philosophy* 22.25 (3 December 1925): 673–688.

Readers of this journal are doubtless studying, or have studied, Professor Dewey's recent book on *Experience and Nature*, certainly the weightiest and most incisive account he has given of his philosophy. In reviewing it, I may therefore be excused from attempting to sum up his chief contentions in his own language, considering especially that his language, as he himself says, is the chief or only obstacle to understanding him. Nor would the fairest paraphrase of his conclusions do him justice. Without the many pointed allusions and incidental insights that humanize his pages, without his constant appeals to the economy of the working mind, many of his positions would remain paradoxes, and it would be impossible to discover the scrupulous fidelity to facts, seen at a certain angle, which dictates his words, even when they seem most unintelligible. Here is a remarkable rereading of things with a new and difficult kind of sincerity, a near-sighted sincerity comparable in philosophy to that of contemporary painters in their painful studies. The intellect here, like the fancy there, arrests its dogmatic vision and stops short at some relational term which was invisible because it is only a vehicle in natural seeing. No wonder that these near elements, abstracted and focused in themselves, have a queer look. For my part, I am entirely persuaded of the genuineness and depth of Dewey's views, within the limits of his method and taken as he means them. He is, fortunately, not without an active band of followers who will be able to interpret and elaborate them in his own spirit. I am hardly in their case, and all I can hope to accomplish is to fix the place and character of this doctrine in relation to the points of view which I instinctively take or which seem to me, on reflection, to be most comprehensive. And I will append such conclusions as I may provisionally reach on this subject to a phrase by which Dewey himself characterizes his system: *Naturalistic Metaphysics*. In what sense is this system naturalistic? In what sense is it metaphysical? How comes it that these two characters (which to me seem contradictory) can be united in this philosophy?

Naturalism is a primary system, or rather it is not a special system at all, but the spontaneous and inevitable body of beliefs involved in animal life, beliefs of which the various philosophical systems are either extensions (a supernatural environment, itself natural in its own way, being added to

nature) or interpretations (as in Aristotle and Spinoza) or denials (as in idealism). Children are interested in their bodies, with which they identify themselves; they are interested in animals, adequate playmates for them, to be bullied with a pleasing risk and a touch of wonder. They are interested later in mechanical contrivances and in physical feats and adventures. This boyish universe is indefinitely extensible on its own plane; it may have heaven around it and fairyland in its interstices; it covers the whole field of possible material action to its uttermost reaches. It is the world of naturalism. On this material framework it is easy to hang all the immaterial objects, such as words, feelings, and ideas, which may be eventually distinguished in human experience. We are not compelled in naturalism, or even in materialism, to ignore immaterial things; the point is that any immaterial things which are recognized shall be regarded as names, aspects, functions, or concomitant products of those physical things among which action goes on. A naturalist may distinguish his own person or self, provided he identifies himself with his body and does not assign to his soul any fortunes, powers, or actions save those of which his body is the seat and organ. He may recognize other spirits, human, animal, or divine, provided they are all proper to natural organisms figuring in the world of action, and are the natural moral transcript, like his own feelings, of physical life in that region. Naturalism may, accordingly, find room for every sort of psychology, poetry, logic, and theology, if only they are content with their natural places. Naturalism will break down, however, so soon as words, ideas, or spirits are taken to be substantial on their own account, and powers at work prior to the existence of their organs, or independent of them. Now it is precisely such disembodied powers and immaterial functions prior to matter that are called metaphysical. Transcendentalism is not metaphysical if it remains a mere method, because then it might express the natural fact that any animal mind is its own center and must awake in order to know anything: it becomes metaphysical when this mind is said to be absolute, single, and without material conditions. To admit anything metaphysical in this sense is evidently to abandon naturalism.

It would be hard to find a philosopher in whom naturalism, so conceived, was more inveterate than in Dewey. He is very severe against the imagination, and even the intellect, of mankind for having created figments which usurp the place and authority of the mundane sphere in which daily action goes on. The typical philosopher's fallacy, in his eyes, has been the habit of hypostatizing the conclusions to which reflection may lead, and depicting them to be prior realities – the fallacy of dogmatism. These conclusions are in reality nothing but suggestions or, as Dewey calls them, "meanings" surrounding the passing experience in which, at some juncture, a person is immersed. They may be excellent in an instrumental capacity, if by their help instinctive action can be enlarged or adjusted more accurately to absent facts; but it would be sheer idolatry to regard them as realities or powers deeper than

obvious objects, producing these objects and afterwards somehow revealing themselves, just as they are, to the thoughts of metaphysicians. Here is a rude blow dealt at dogma of every sort: God, matter, Platonic ideas, active spirits, and creative logics all seem to totter on their thrones; and if the blow could be effective, the endless battle of metaphysics would have to end for lack of combatants.

Meantime there is another motive that drives Dewey to naturalism: he is the devoted spokesman of the spirit of enterprise, of experiment, of modern industry. To him, rather than to William James, might be applied the saying of the French pragmatist, Georges Sorel, that his philosophy is calculated to justify all the assumptions of American society. William James was a psychologist of the individual, preoccupied with the varieties of the human imagination and with the possible destinies of the spirit in other worlds. He was too spontaneous and rare a person to be a good mirror of any broad general movement; his Americanism, like that of Emerson, was his own and within him, and perhaps more representative of America in the past than in the future. In Dewey, on the contrary, as in current science and ethics there is a pervasive quasi-Hegeian tendency to dissolve the individual into his social functions, as well as everything substantial or actual into something relative or transitional. For him events, situations, and histories hold all facts and all persons in solution. The master-burden of his philosophy, which lends it its national character, is a profound sympathy with the enterprise of life in all lay directions, in its technical and moral complexity, and especially in its American form, where individual initiative, although still demanded and prized, is quickly subjected to overwhelming democratic control. This, if I am not mistaken, is the heart of Dewey's pragmatism, that it is the pragmatism of the people, dumb and instinctive in them, and struggling in him to a labored but radical expression. His pragmatism is not inspired by any wish to supply a new argument to support some old speculative dogma. Nor is he interested, like Nietzsche and Vaihinger, in a heroic pessimism, desperately living as if postulates were true which it knows to be false. He is not interested in speculation at all, balks at it, and would avoid it if he could; his inspiration is sheer fidelity to the task in hand and sympathy with the movement afoot: a deliberate and happy participation in the attitude of the American people, with its omnivorous human interests and its simplicity of purpose.

Now the philosophy by which Americans live, in contrast to the philosophies which they profess, is naturalistic. In profession they may be Fundamentalists, Catholics, or idealists, because American opinion is largely pre-American; but in their hearts and lives they are all pragmatists, and they prove it even by the spirit in which they maintain those other traditional allegiances, not out of rapt speculative sympathy, but because such allegiance seems an insurance against moral dissolution, guaranteeing social cohesion and practical success. Their real philosophy is the philosophy of enterprise.

Now enterprise moves in the infinitely extensible boyish world of feats and discoveries – in the world of naturalism. The practical arts, as Dewey says, assume a mechanical unity and constancy established in the universe. Otherwise discoveries made to-day would not count to-morrow, inventions could not be patented, the best-laid plans might go astray, all work might be wasted, and the methods of experts could not be adjusted more and more accurately to their tasks. This postulated mechanical system must evidently include the hands and brain of the worker, which are intertwined inextricably with the work done. It must also include his mind, if his mind is to be of any practical account and to make any difference in his work. Hence the implicit American philosophy, which it is Dewey's privilege to make explicit, involves behaviorism. This doctrine is new and amazing if taken to deny the existence of thought; but on its positive side, in so far as it puts all efficient processes on one level, it has been an implication of naturalism from time immemorial. For a naturalist nothing can be substantial or efficacious in thought except its organs and instruments, such as brains, training, words, and books. Actual thought, being invisible and imponderable, eludes this sort of chase. It has always been rather ignored by materialists; but it remained for American optimists to turn their scorn of useless thought into a glad denial of its existence. This negative implication of behaviorism follows also from the commonsense view that mind and body act upon each other alternately; for when this view is carried out with empirical rigor, it corrects the speculative confusion which first suggested it. What it called mind turns out never to have been anything but a habit in matter, a way people have of acting, speaking, and writing. The actuality of spirit, mystically momentary, does not fall within the purview of this empirical inventory any more than the realm of truth, invisibly eternal. Men of affairs, who can easily tell a clever man from a fool, are behaviorists by instinct; but they may scout their own conviction when it is proposed to them by philosophers in paradoxical language. The business intellect, by the time it comes to theorizing, is a little tired. It will either trust a first impression, and bluff it out, or else it will allow comfortable traditional assurances in these hazy regions to relieve it of responsibility.

Is Dewey a behaviorist? On the positive side of the theory, he certainly is; and it is only when we interpret what he says about ideas, meanings, knowledge, or truth behavioristically, that the sense and the force of it begin to appear. Often, indeed, he seems to jump the barrier, and to become a behaviorist in the negative sense also, denying the existence of thought: because it would be to deny its existence if we reduced it to its material manifestations. At least at one point, however, the existence of thought in its actuality and spiritual concentration is admitted plainly. Not, indeed, on the ground which to most philosophers would seem obvious and final, namely, that people sometimes do actually feel and think. This consideration might seem to Dewey irrelevant, because actual feeling and thinking are accounted

for initially, on his view, by the absolute existence of the specious or conventional world: they do not need to be introduced again among its details. An impersonal transcendental spectator, though never mentioned, is always assumed; and the spectacle of nature unrolled before him may be, and strictly speaking must be, wholly observable and material. There can not be any actual mind in experience except the experience itself. The consideration which nevertheless leads Dewey to graft something consciously actual and spiritual upon the natural world is of quite another sort. Essentially, I suspect, it flows from his choice of "events" to be his metaphysical elements (of which more presently); incidentally it is attached to the sympathetic study which he has made of Aristotle. Events, he thinks, have natural "endings," "culminations," or "consummations." They are not arbitrary sections made in the flux of nature, as if by geometrical planes passed across the current of a river. They are natural waves, pulsations of being, each of which, without any interruption in its material inheritance and fertility, forms a unit of a higher order. These units (if I may express the matter in my own language) fall sometimes into the realm of truth, when they are simply observable patterns or rhythms, and sometimes into the realm of spirit, as in animal perception or intent, when the complex tensions of bodily or social life generate a single sound, an actual pang, or a vivid idea. Mind at such moments possesses a hypostatic spiritual existence, over and above the whole behaviorist or pragmatic ground-work of mind: it has become conscious, or as Aristotle would say, has reached its second entelechy and become intellect in act. This hypostatic spiritual existence Dewey seems to recognize at least in esthetic contemplation; but evidently every actual feeling or idea, however engrossed in action or however abstractly intellectual, is in the same case. Such an admission, if taken to heart, would have leavened this whole philosophy; but Dewey makes it grudgingly, and hastens to cover it up. For instance, when he comes upon the phrase "Knowledge of acquaintance," a phrase intended to express just such instant innocent immediate perusal of essence, he refuses to understand it as it was meant, and says that acquaintance implies recognition and recognition familiarity; on the ground, I suppose, that people are called "acquaintances" when they bow to one another: and we are left with an uncomfortable suspicion that it is impossible to inspect anything for the first time. In another place we are told that consummations are themselves fruitful and ends are also means. Yes, but in what sense? Of course, no earthly flame is so pure as to leave no ashes, and the highest wave sinks presently into the trough of the sea; but this is true only of the substance engaged, which, having reached a culmination here, continues in its course; and the habit which it then acquired may, within limits, repeat the happy achievement, and propagate, the light. One torch by material contact may kindle another torch; and if the torches are similar and the wind steady, the flames, too, may be similar and even continuous; but if anyone says that the

visible splendor of one moment helps to produce that of another, he does not seem ever to have seen the light. It will therefore be safer to proceed as if the realm of actual spirit had not been broached at this point, and as if the culminations recognized were only runs or nodes discoverable in nature, as in the cycle of reproduction or in sentences in discourse. The behaviorist landscape will then not be split by any spiritual lightning, and naturalism will seem to be established in its most unqualified form. Yet in this case how comes it that Dewey has a metaphysics of his own, that cosmology is absent from his system, and that every natural fact becomes in his hands so strangely unseizable and perplexing?

This question, which is the crux of the whole system, may be answered, I think, in a single phrase: *the dominance of the foreground*. In nature there is no foreground or background, no here, no now, no moral cathedra, no centre so really central as to reduce all other things to mere margins and mere perspectives. A foreground is by definition relative to some chosen point of view, to the station assumed in the midst of nature by some creature tethered by fortune to a particular time and place. If such a foreground becomes dominant in a philosophy naturalism is abandoned. Some local perspective or some casual interest is set up in the place of universal nature or behind it, or before it, so that all the rest of nature is reputed to be intrinsically remote or dubious or merely ideal. This dominance of the foreground has always been the source of metaphysics; and the metaphysics has varied according as the foreground has been occupied by language or fancy or logic or skeptical self-consciousness or religious rapture or moral ambition. Now the dominance of the foreground is in all Dewey's traditions: it is the soul of transcendentalism and also of empiricism; it is the soul of moralist and of that kind of religion which summons the universe to vindicate human notions of justice or to sub serve the interests of mankind or of some special nation or civilization. In America the dominance of the foreground is further emphasized by the prevalent absorption in business life and in home affections, and by a general feeling that anything ancient, foreign, or theoretical can not be of much consequence.[1] Pragmatism may be regarded as a synthesis of all these ways of making the foreground dominant: the most close reefed of philosophical craft, most tightly hugging appearance, use, and relevance to practice today and here, least drawn by the lure of speculative distances. Nor would Dewey, I am sure, or any other pragmatist, ever be a naturalist instinctively

[1] I can imagine the spontaneous pragmatism of some President of a State University, if obliged to defend the study of Sanskrit before a committee of Senators. "You have been told," he would say, "that Sanskrit is a dead language. Not at all: Sanskrit is Professor Smith's Department, and growing. The cost is trifling, and several of our sister universities are making it a fresh requirement for the Ph.D. in classics. That, Gentlemen, is what Sanskrit *is*."

or on the wings of speculative insight, like the old Ionians or the Stoics or Spinoza, or like those many mystics, Indian, Jewish, or Mohammedan, who, heartily despising the foreground, have fallen in love with the greatness of nature and have sunk speechless before the infinite. The pragmatist becomes, or seems to become, a naturalist only by accident. When as in the present age and in America the dominant foreground is monopolized by material activity; because material activity, as we have seen, involves naturalistic assumptions, and have been the teacher and the proof of naturalism since the beginning of time. But elsewhere and at other periods experience is free to offer different perspectives into which the faithful pragmatist will be drawn with equal zeal; and then pragmatic metaphysics would cease to be naturalistic and become, perhaps, theological. Naturalism in Dewey is accordingly an assumption imposed by the character of the prevalent arts; and as he is aware that he is a naturalist only to that extent and on that ground, his naturalism is half-hearted and short-winded. It is the specious kind of naturalism possible also to such idealists as Emerson, Schilling, or any Hegelian of the Left, who may scrupulously limit their survey, in its range of objects, to nature and to recorded history, and yet in their attitude may remain romantic, transcendental, piously receiving as absolute the inspiration dominating moral life in their day and country. The idealists, being self-conscious, regarded this natural scene as a landscape painted by spirit; Dewey, to whom self-consciousness is anathema, regards it as a landscape that paints itself; but it is still something phenomenal, all above board. Immediacy, which was an epistemological category, has become a physical one: natural events are conceived to be compounded of such qualities as appear to human observers, as if the character and emergence of these qualities had nothing to do with the existence, position, and organs of those observers. Nature is accordingly simply experience deployed, thoroughly specious and pictorial in texture. Its parts are not (what they are in practice and for living animal faith) substances presenting accidental appearances. They are appearances integrally woven into a panorama entirely relative to human discourse. Naturalism could not be more romantic: nature here is not a world but a story.

We have seen that the foreground, by its dominance, determines whether the empirical philosopher shall be provisionally a naturalist or shall try being something else. What now, looked at more narrowly, is the character of this foreground? Its name is Experience; but lest we should misunderstand this ambiguous word, it is necessary to keep in mind that in this system experience is impersonal. It is not, as a literary psychologist might suppose, a man's feelings and ideas forming a life-long soliloquy, his impressions of travel in this world. Nor is it, as a biologist might expect, such contact of sensitive animals with their environment as adapts them to it and teaches them to remember it. No: experience is here taken in a transcendental, or rather in a moral, sense, as something romantically absolute and practically coercive.

There exists a social medium, the notorious scene of all happenings and discoveries, the sum of those current adventures in which anybody might participate. Experience is deputed to include everything to which experience might testify: it is the locus of public facts. It is therefore identical with nature, to the extent and in the aspects in which nature is disclosed to man. Death, for instance, should be set down as a fact of experience. This would not be possible if experience were something personal, unless indeed death was only a transition to another life. For so long as a man's sensations and thoughts continue, he is not dead and when dead he has no more thoughts or sensations. But is such actual death, we may ask, the death that Dewey can have in mind? The only death open to experience is the death of others (here is a neat proof of immortality for those who like it); and death, for the pragmatist, simply *is* burial. To suppose that a train of thoughts and feelings going on in a man invisibly might at last come to an end, would be to place the fact of death in a sphere which Dewey does not recognize, namely, in the realm of truth; for it would simply be true that the man's thoughts had ceased, although neither he nor anybody else could find that fact in experience. For other people it would remain a fact assumed and credited, for him it would be a destiny that overtook him. Yet Experience, as Dewey understands it, must include such undiscoverable objects of common belief, and such a real, though unobserved, order of events. The dominant foreground which he calls Experience is accordingly filled and bounded not so much by experience as by convention. It is the social world.

How conventional this foreground is will appear even more clearly if we note the elements which are said to compose it. These are events, histories, situations, affairs. The words "affairs" and "situations," in their intentional vagueness, express very well the ethical nerve of this philosophy; for it is essentially a moral attitude or a lay religion. Life is a practical predicament; both necessity and duty compel us to do something about it, and also to think something about it, so as to know what to do. This is the categorical imperative of existence; and according to the Protestant tradition (diametrically opposed to the Indian) the spirit, in heeding its intrinsic vocation, is not alienated from earthly affairs, but on the contrary pledges itself anew to prosecute them with fidelity. Conscience and nature here exercise their suasion concurrently, since conscience merely repeats the summons to enter a field of responsibility – nature – formed by the deposit of it past labors. The most homely business, like the widest policies, may be thus transfused with a direct metaphysical inspiration; and although Dewey avoids all inflated eloquence on this theme, it is clear that his philosophy of Experience is a transcendental moralism. The other two terms, however, "events" and "histories," point to the flux of matter, although this is still gathered up and subdivided under units of discourse. "Event" is now a favorite word among philosophers who are addressed to the study of nature, but bring with them

an empirical logic; and it well expresses that conjunction. An event does not involve a spectator, and does involve an environment on the same plane as the event: so far events belong directly to the flux of nature. At the same time an event is a change, and all the dialectic of change applies to the conception. Are events the crises between existence characterized in one way and existence characterized in another way? Or are events the intervals between such crises? But if these intervals, each having a somewhat different quality, were taken separately, they would not lodge in a common space or time; there would be no crises between them, no change, and (as I think would appear in the end) they themselves would have no existence. If events are to be successive, and fragments of the flux of nature, they must be changes in an abiding medium. In other words, an event, in its natural being, is a mode of substance, the transit of an essence. Moreover, natural events would have to be microscopic, because intervals containing no internal crisis, however long or even eternal they might seem sentimentally, could not be measured and would count as instants. This corollary is well fitted to remind us that nature laughs at our dialectic and goes on living in her own way. Her flux, like the flow of a river, is far more substantial than volatile, all sleepy continuity, derivation, persistence, and monotony. The most ordinary form of change in her – perhaps the only fundamental form – is motion; and it would be highly artificial to call the parts of a motion events where there are no crises and no intervals. Even night and day, unless we choose a particular point on the earth's surface for our station, are not events, since both are perpetual. It is apparently only on higher levels, genetically secondary, that nature produces events, where movement becomes rhythmical, and a culmination is followed by a breakdown and a repetition, as in animal birth and death. These secondary rhythms naturally attract the attention of a human observer, whose units of perception are all impressionistic and pictorial; he selects events from the vast continuities of nature because they go with rhythms in his own organism, with which his intuitions – the only vital culminations – are conjoined. Hence the empirical impression that nature is a series of events, although if they were mere events they could not be parts of nature, but only essences succeeding one another before vacant attention or in discourse; in other words, we should be in the mock world of psychologism.

The superficial level proper to empirical events becomes even more obvious if instead of calling them events we call them histories. The parts of nature seem events when we ignore their substance and their essence and consider only their position; anything actual is an event only, so to speak, at its margins, where it ceases to be itself. But before the parts of nature can seem to be histories, we must impose on them dramatic unities fetched from a far more derivative sphere. Histories are moral units, framed by tracing the thread of some special interest through the maze of things, units impossible to discriminate before the existence of passions and language. As there is a

literary psychology which represents the mind as a mass of nameable pictures and describable sentiments, so there is a romantic metaphysics which hypostatizes history and puts it in the place of nature. "Histories" bring us back into the moral foreground where we found "situations" and "affairs." The same predicaments of daily life are viewed now in a temporal perspective, rather than as they beset us at any one moment.

That the foreground of human life is necessarily moral and practical (it is so even for artists) and that a philosophy which limits itself to clarifying moral perspectives may be a very great philosophy, has been known to the judicious since the days of Socrates. Why could not Dewey have worked out his shrewd moral and intellectual economy within the frame of naturalism, which he knows is postulated by practice, and so have brought clearness and space into the picture, without interposing any metaphysics? Because it is an axiom with him that nothing but the immediate is real. This axiom, far from being self-evident, is not even clear: for everything is "real" in some sense, and there is much doubt as to what sort of being is immediate. At first the axiom produced psychological idealism, because the proudly discoursing minds of philosophers took for granted that the immediate for each man could be only his own thoughts. Later it has been urged (and, I think, truly) that the immediate is rather any object – whether sensible or intelligible makes no difference – found lying in its own specious medium; so that immediatism is not so much subjective as closely attentive and mystically objective. Be it noted, however, that this admitted objectivity of real things remains internal to the immediate sphere: they must never be supposed to possess an alleged substantial existence beyond experience. This experience is no longer subjective, but it is still transcendental, absolute, and groundless; indeed it has ceased to seem subjective only because it seems unconditioned; and in order to get to the bottom and to the substance of anything, we must still ask with Emerson, What is this *to me*, or with William James, What is this *experienced as*. As Dewey puts it, these facts of experience simply *are* or *are had*, and there is nothing more to say about them. Such evidence flooding immediate experience I just now called mystical, using the epithet advisedly; because in this direct possession of being there is no division of subject and object, but rapt identification of some term, intuition of some essence. Such is sheer pleasure or pain, when no source or object is assigned to it; such is esthetic contemplation; such is pure thinking, the flash of intellectual light. This mystical paradise is indefinitely extensible, like life, and far be it from me to speak evil of it; it is there only that the innocent spirit is at home. But how should pragmatism, which is nothing if not prehensile, take root in this Eden? I am afraid pragmatism is the serpent; for there is a forbidden tree in the midst, the tree of Belief in the Eventual, the fruit of which is Care; and it is evident that our first parents must have partaken of it copiously; perhaps they fed on nothing else. Now when immediate experience is crossed by Care

it suffers the most terrible illusion, for it supposes that the eventual about which it is troubled is controllable by the immediate, as by wishes, omens, or high thoughts; in other words, that the essences given in the immediate exist, generate their own presence, and may persist and rearrange themselves and so generate the future. But this is sheer superstition and trust in magic; the philosophy not of experience but of inexperience. The immediate, whether paradise or a hell, is always specious; it is peopled by specters which, if taken for existing and working things, are illusions; and although they are real enough, in that they have definite character and actual presence, as a dream or a pain has, their reality ends there; they arc unsubstantial, volatile, leaving no ashes, and their existence, even when they appear, is imputed to them by a hidden agency, the demon of Care, and lies wholly in being perceived. Thus immediate experience of things, far from being fundamental in nature, is only the dream which accompanies our action, as the other dreams accompany our sleep; and every naturalist knows that this waking dream is dependent for its existence, quality, intensity, and duration on obscure processes in the living body, in its interplay with its environment; processes which go back, through seeds, to the first beginnings of life on earth. Immediate experience is a consummation; and this not in esthetic contemplation alone, but just as much in birth-pangs or the excitement of battle. All its episodes, intermittent and wildly modulated, like the sound of wind in a forest, are bound together and rendered relevant to one another only by their material causes and instruments. So tenuous is immediate experience that the behaviorist can ignore it altogether, without inconvenience, substituting everywhere objects of conventional belief in their infinite material plane. The immediate is, indeed, recognized and prized only by mystics, and Dewey himself is assured of possessing it only by virtue of his social and ethical mysticism, by which the whole complex theater of contemporary action seems to him to be given immediately: whereas to others of us (who are perhaps mystical at other points) this world of practice seems foreign, absent from our better moments; approachable even at the time of action only by animal faith and blind presumption, and compacted, when we consider its normal texture, out of human conventions, many of them variable and foolish. A pragmatist who was not an ethical or social mystic, might explore that world scientifically, as a physician, politician, or engineer, and remain throughout a pure behaviorist or materialist, without noticing immediate experience at all, or once distinguishing what was given from what was assumed or asserted. But to the mystic, if he is interested in that world, it all comes forward into the immediate; it becomes indubitable, but at the same time vague; actual experience sucks in the world in which conventional experience, if left to dogmatize, would have supposed it was going on; and a luminous cloud of immediacy envelops everything and arrests the eye, in every direction, on a painted perspective; for if any object becomes immediate, whatever it may be,

it becomes visionary. That same spiritual actuality which Dewey, in passing, scarcely recognized at the top of animal life, he now comes upon from within, and without observing its natural locus, lays at the basis of the universe. The universe, in his system, thereby appears inverted, the accidental order of discovery being everywhere substituted for the natural order of genesis; and this with grave consequences, since it is not so easy for the universe as for an individual to stand on its head.[2]

Consider, for instance, the empirical status of the past. The only past that ever *is* or *is had* is a specious past, the fading survival of it in the present. Now the form which things wear in the foreground, according to this philosophy, is their *real* form; and the meaning which such immediate facts may assume hangs on their use in executing some living purpose. What follows in regard to past time? That the survival or memory of it comprises all its reality, and that all the meaning of it lies in its possible relevance to actual interests. A memory may serve as a model or condition in shaping some further enterprise, or may be identified with a habit acquired by training, as when we have learned a foreign language and are ready to speak it. Past experience is accordingly real only by virtue of its vital inclusion in some present undertaking, and yesterday is *really* but a term perhaps useful in the preparation of tomorrow. The past, too, must work if it would live, and we may speak without irony of "the futurity of yesterday" in so far as yesterday has any pragmatic reality.

This result is consistent with the general principle of empirical criticism by which we are forbidden to regard God, truth, or the material cosmos as anything but home vistas. When this principle is applied to such overwhelming outer realities, it lightens the burden of those who hate external compulsions or supports; they can henceforth believe they are living in a moral universe that changes as they change, with no sky lowering over them save a portable canopy which they carry with them on their travels. But now this

[2] A curious reversal of the terms "natural" and "ideal" comes about as we assume that the immediate is substantial or that it is visionary. Suppose I say that "everything ideal emanates from something natural." Dewey agrees, understanding that everything remote emanates from something immediate. But what I meant was that everything immediate – sensation, for instance, or love – emanates from something biological. Not, however, (and this is another verbal snare) from the concepts of biological science, essences immediately present to the thoughts of biologists, but from the largely unknown or humanly unknowable process of animal life. I suppose we should not call some of our ideas scientific if they did not trace the movement of nature more accurately and reliably than do our random sensations or dramatic myths; they are therefore presumably truer in regard to those distributive aspects of nature which they select. But science is a part of human discourse, and necessarily poetical, like language. If literal truth were necessary (which is not the case in practice in respect to nature) it would be found only, perhaps, in literature – in the reproduction of discourse by discourse.

pleasant principle threatens the march of experience itself: for if my ancestors have no past existence save by working in me now, what becomes of my present being, if ever I cease to work in my descendants? Does experience today draw its whole existence from their future memories? Evidently this can not be the doctrine proposed; and yet if it be once admitted that all the events in time are equally real and equally central, then at every point there is a by-gone past, intrinsically perfectly substantial and self-existent; a past which such memories or continuations as may be integral to life at this later moment need continue only very partially, or need recover only schematically, if at all. In that case, if I ever find it convenient to forget my ancestors, or if my descendants find it advantageous to forget me, this fact might somewhat dash their vanity or mine if we should hear of it, but can not touch our substantial existence or the truth of our lives. Grant this, and at once the whole universe is on its feet again; and all that strange pragmatic reduction of yesterday to tomorrow, of Sanskrit to the study of Sanskrit, of truth to the value of discovering some truth, and of matter to some human notion of matter, turns out to have been a needless equivocation, by which the perspectives of life, avowedly relative, have been treated as absolute, and the dominance of the foreground has been turned from a biological accident into a metaphysical principle. And this quite wantonly: because practice, far from suggesting such a reduction, precludes it, and requires every honest workman to admit the democratic equality of the past and the future with the present, and to regard the inner processes of matter with respect and not with transcendental arrogance. The living convictions of the pragmatist himself are those involved in action, and therefore naturalistic in the dogmatic sense; action involves belief, belief judgment, and judgment dogma; so that the transcendental metaphysics and the practical naturalism of the pragmatist are in sharp contradiction, both in logic and in spirit. The one expresses his speculative egotism, the other his animal faith.

Of course, it is neither Dewey nor the pragmatic school that is to blame for this equivocation; it is a general heirloom, and has infected all that criticism of scholastic dogma on which modern philosophy is founded. By expressing this critical principle more thoroughly, the pragmatists have hoped to clear the air, and perhaps ultimately may help to do so. Although I am myself a dogmatic naturalist, I think that the station assumed by Dewey, like the transcendental station generally, is always legitimate. Just as the spirit has a right to soliloquize, and to regard existence as a strange dream, so any society or nation or living interest has a right to treat the world as its field of action, and to recast the human mind, as far as possible, so as to adapt it exclusively to that public function. That is what all great religions have tried to do, and what Sparta and Carthage would have done if they had produced philosophers. Why should not America attempt it? Reason is free to change its logic, as language to change its grammar; and the critic of the life of reason

may then distinguish, as far as his penetration goes, how much in any such logic or grammar is expressive of material circumstances, how much is exuberant rhetoric, how much local, and how much human. Of course, at every step such criticism rests on naturalistic dogmas; we could not understand any phase of human imagination, or even discover it, unless we found it growing in the common world of geography and commerce. In this world fiction arises, and to this world it refers. In so far as criticism can trace back the most fantastic ideas – mythology, for instance – to their natural origin, it should enlighten our sympathies, since we should all have lived in the society of those images, if we had had the same surroundings and passions; and if in their turn the ideas prevalent in our own day can be traced back to the material conditions that bred them, our judgment should be enlightened also. Controversy, when naturalism is granted, can yield to interpretation, reconciling the critical mind to convention, justifying moral diversity, and carrying the sap of life to every top-most intellectual flower. All positive transcendental insights, whether empirical, national, or moral, can thus be honored (and disinfected) by the baldest naturalism, remaining itself international, Bohemian, and animal. The luminous fog of immediacy has a place in nature; it is a meteorological and optical effect, and often a blessing. But why should immediacy be thought to be absolute or a criterion of reality? The great error of dogmatists, in hypostatizing their conclusions into alleged preexistent facts, did not lie in believing that facts of some kind preexisted; the error lay only in framing an inadequate view of those facts and regarding it as adequate. God and matter are not any or all the definitions which philosophers may give of them: they are the realities confronted in action, the mysterious but momentous background, which philosophers and other men mean to describe by their definitions or myths or sensible images. To hypostatize these human symbols, and identify them with matter or with God, is idolatry: but the remedy for idolatry is not iconoclasm, because the senses, too, or the heart or the pragmatic intellect, can breed only symbols. The remedy is rather to employ the symbols pragmatically, with detachment and humor, trusting in the steady dispensations of the substance beyond.

ADVENTITIOUS ASPECTS OF ESSENCE

George Santayana. "Adventitious Aspects of Essence." *The Realm of Essence* (New York: Charles Scribner's Sons, 1927), chap. 3, pp. 26–44.

The realm of essence, like the empyrean, is a clear and tranquil region when you once reach it; but for the observer from the earth clouds may intervene, or his eye may be arrested at some nearer sphere which, just because it has some opaqueness, he may think the true blue. Instead of conceiving essences he may conceive possible beings, problematical facts, and forms of things, abstractions, thoughts, sensations, or natural elements. Of course such intermediate objects, however they be defined, will exhibit some essence, since some essence cannot help appearing in any chosen thing whatsoever; but in the categories just mentioned there is some ambiguity, some reference to contingent existence, which limits their scope, and renders them altogether confusing, if taken as synonyms for essential being.

The word "possible" is slippery and treacherous. It is commonly applied to anything that the speaker can readily imagine, especially when he is ignorant whether it is a fact or not. In this sense the whole future, and much of the past, is called possible when imaginable. But in another sense the whole past and future, even when unimaginable, must have been possible too. The materially possible threatens to coincide with the actual course of nature: and then the term possible begins to mean the materially impossible, provided it is imaginable. The imagination, however, is itself something existent, and extremely elastic: a little shake, or a new stimulus, will cause it to conceive many new possibilities. Can these have been impossibilities before? Perhaps we may take refuge in the notion that everything is possible except what is self-contradictory: in other words, things are not possible merely because they are actual, or merely because they are imagined, but if they are such as not to preclude being imagined. But how should anything preclude being imagined, if an imagination arose capable of imagining it? The meaning can only be that my own imagination, in some particular instance, has got into a tangle, and that in speaking of the round square or of the son of a barren woman I have lost the meaning of my terms; and what I call an impossibility is only the suspense of my thought between two possibilities. Nothing contradicts itself, not even this state of confusion in my thinking. It is a perfectly possible muddle. This process of fluctuating from one object to another has a character easily recognizable; its essence, like every essence, is individual and

(since it may reappear) is universal. Contradiction is a vice into which discourse may fall when it blurs the inherent distinctness of different essences. Determination, individuality, variety infinitely precise and indelible (degrees of articulation being themselves all equally distinct) is the very being of essence. Howsoever monistic physics may choose to be, the realm of essence is the home of eternal and irreducible plurality.

The terms "possible" and "impossible" have, then, no proper application in the realm of essence; even to facts in nature they are applicable only in view of human ignorance or imagination. Their true field is that of discourse, where the intent to consider one essence binds the mind to fidelity and consistency, and excludes the substitution of another essence under the same name – excludes it, I mean, if the intent is maintained to express the essence originally chosen. Hence the extension of the "possible" and the "impossible" to natural facts, in so far as their names or relations are assumed to prejudge their character: in a given world, describable by a given essence, anything contrary to that essence is impossible. In the actual universe, its essence being completely determined by the events which compose it, all that is actual is necessary and all else is impossible. But this of course does not preclude the possibility of any different world; and so long as the complete essence of the actual universe is unknown to us, we may give its name to almost any extensions or transformations of the part which we presume to know: so that the known world will be free to become, or to have been, almost anything.

The contingency of existence, though intrinsic to it, and the hypothetical nature of all reasoning about it, are a trial to logicians: they would like their art to rule *a priori*. Many of them, in their eagerness to make logic dominant, betray it, by reducing it to a description of what they presume to be the natural movement of thought or of history: but there are some too devoted and clear-headed for such a subterfuge, who nevertheless wish to chain existence to their chariot. How do so? I know only of one way: to assert that the whole realm of essence is realized in existence. The existence of infinity of worlds irrelevant to ours, and utterly undiscoverable by us, cannot be precluded by our ignorance of them: the supposition is merely idle. But another consequence involved in this hypothesis is positively repugnant to common sense; and this is, that an infinity of worlds almost identical with ours, but differing from it in some detail, must exist too. An infinite number of solar systems, for instance, must have begun as ours began, but each of them must have deviated at one point from ours in its evolution, all the previous incidents being followed, in each case, by a different sequel. The interest in natural derivation which animates the observant and artful mind is thus outraged by the demand for logical completeness in things: and there can be little doubt to which side the sense for fact, which alone can judge of facts, will incline the naturalist.

By a somewhat different opposition to accidental facts, essence might be called "the imaginary." This designation is popular and poetically very

appropriate, since the realm of essence is unsubstantial, remote from existence, and infinitely more extensive. In broaching it we escape the limitations of fortune, as the poet does in his fictions; and yet the objects that greet us there may be more definite, memorable, and beautiful than the sordid facts, which we live among without feeling for them, perhaps, any intellectual affinity. But the danger in calling essence imaginary is that, like poetry, we should identify it with the imagined. The imagined is indeed unsubstantial, but it is selected, insecure, and dependent for its specious actuality on the vapors of some animal psyche The imagined is not, as essence is, a field from which all facts must gather their temporary forms; it is only a replica or variant of some of these facts – namely, of human sensations – richer perhaps in spots than material reality, but on the whole far thinner and less extensive. Images drifting through idle heads are in their psychological dimension a part of the actual, since the intuition of those imaginary objects occurs at definite times and places. The imaginary, if it is to mean essence, is the infinite fairy-land of which such dreams are glimpses. The moral connotation of the word imaginary is also ambiguous. Actual images, being generated in the living psyche, may be very apposite fulfillments to her previous experience or to her instinctive needs, and therefore very beautiful; and actual dreams, even if for the most part silly and fatiguing, are sometimes pleasant and even prophetic. Nothing of the sort can be said of the imaginary as a whole, conceived as the realm of essence. Not being selected or produced by any living soul, but inert, infinite, and latent, it contains an appalling multitude of vain and ugly themes, as well as the few which are relevant to human interests and fit for human contemplation.

If free imagination presents stray essences to the mind, attentive perception presents others, to which studious people give greater importance. The flux of nature could not be a flux, nor at all perceptible, unless it was a flux through essences, that is, through forms of being differing from one another. It is as the forms things wear to the senses or to the practiced intellect that essences are first noticed; in this capacity, or as definitions of current terms, they appear in the Socratic school. Geometrical figures, fixed by intent, are certainly essences; so too are any types of animal bodies or human institutions which may be arrested in thought: but so also are all the qualities of sensation despised by Platonism and all the types of change or relation neglected by that philosophy. This neglect was ominous, because if essences had been studied for their own sake they would have been found everywhere, as they are by the poet or the mathematician. To discern them only in natural or moral units, and to think of them as perfections towards which things aspire, is not merely to omit noticing them elsewhere but to regard them as natural magnets, as a background of metaphysical powers, more selective than nature itself, and constituting a world of substances behind the flux of appearance. Physics and theology may appeal to such patron substances if they think fit;

but in the theory of essence they have no place whatever. Essences are not substances containing a matter that can assume a different essence: they cannot be the material source of anything. Nor have they any relevance to particular places and times, so that one might be conceived to preside over one part of nature, and another over another. The essence of a bridge cannot build bridges or breed them; and when a bridge falls and the matter of it becomes a heap of stones, the essence of that bridge is not a surviving ghost haunting the spot, and seeking to restore the structure. A material bridge-builder must return to the work: and the resulting form will hardly repeat exactly the one that has disappeared; nor will that discarded essence fight against reform, or in any way complain or avenge itself, if presently bridge-builders come no more to the spot, and the placid stream flows on unspanned, reflecting no shadow of any human contrivance. So it is also, in spite of superstition, with the essences of living beings, which reproduce themselves for generations with little change of type. Their conservation is physical and an elaborate instance of rhythm and habit in matter. Here too a material seed must transmit the substance that is to run through the ancestral cycle and embody that familiar essence: let the seed fail, or circumstances modify it, and at once that prescribed form is forsaken and forgotten, relegated to the realm of essence and reduced to the same impotence, or left in the same peace, as all its sister essences that time has never brought to existence.

The most stubborn misunderstanding of essence arises, however, from thinking and calling it an abstraction. In a popular sense the epithet is natural and harmless: it means only that essence is immaterial. So mathematics is called an abstract science and music an abstract art; they do not describe particular parts of the material world or particular historical events; they may therefore seem unreal and superfluous to the man in the street. But the mathematician or the musician will hardly call them *abstract*, since his apprehension of them is direct and his interest in them primary. No doubt the material world, especially in his own person and life, supplies a suggestion and an organ for those intuitions; but their object is so far from being drawn out of existing things that it never exists in them in its ideal perfection, and the study of it requires a special imaginative faculty, a profound application, and a great exactitude. It is the very complexity and precise definition of this realm – its essential concreteness – that renders it difficult and vague to the gross mind: and it is called abstract not because it is drawn from existence but because it is not found there.

It is an accident to essence to be manifested; but not to be manifested is also an accident; it means simply that matter or intellect happen never to have traversed that form. A different plasticity in existence might make any essence an appearance; and evidently in a given appearance there can be nothing abstract – nothing verbal, unrealizable, or cognitively secondary. Each appearance (and therefore every essence, since it might well appear) is an

obvious and complete being; and if essences when simple are indefinable, that fact only proves that they are the original elements of any description. Far from being creatures of language, they suffer from not being commonly named, since names are hurriedly clapped on things and persons, however ill perceived, which move as material units; whereas the most evident features in immediate experience receive no separate names, until perhaps some logician, poet, or madman grows conscious of their perpetual presence, and borrows some title for them from the vocabulary of physics; as I have borrowed this term "essence," once used by chemists for their drugs, in order to designate every specious object actually present to intuition. Language is responsible, not for these objects, but for the prejudice against them. An essence, if un-named, is thought to be imperfect and but half real. An unchristened child has to be called So-and-So's baby, and a stranger in the street has to be pointed at dumbly; yet it would be too egotistical even for human nature to assert that the waif or the stranger possessed no being of his own, but was essentially an abstraction from our social circle, because he could be described in our language only relatively and peripherally. It is not otherwise with the immediate, radical, nameless phantoms of feeling and intuition. They are just the appearances they are, exactly determinate and perfect at each moment, and different in some precise way from whatever else may be felt before or after or by other people; and the necessary defects, or rather the proper summary function, of language or reflection, must not be charged against those primary appearances as a defect of essence.

When a term is felt to be disparaging, as the term abstract has become for some writers, it can easily be passed on from one bad thing to another. Instead of designating defect of form abstractness may designate defect of quantity. In an etymological sense any part of a thing, like the skin of an apple when peeled off, might be called an abstraction from the whole, especially when the part abstracted happens not to have existed separately in the beginning, as do the bricks of a house, but to have grown up together with the whole, and been first found there. Hence a well-known doctrine that only the Absolute is concrete and that every particular fact or observation is an abstraction. In this sense of the word, every essence would be an abstraction from the realm of essence, but no essence, much less the realm of essence in its entirety, would be an abstraction from existing things: on the contrary, existing things would be abstractions from their essences, which in the realm of essence possess much richer essential relations than those which in existing instances are abstracted and realized materially. The rind of the apple, peeled and curling casually on a plate, would be a miserable abstraction from all the spirals and all the patterns implied in its geometrical essence and in its pictorial aspect.

Abstraction, however, in the proper sense of the word, is possible only for a mind: things and essences, whatever may be their unions or separations, are

never in their own being abstractions from anything else. A term can be abstract only relatively: how should anything be abstract in itself? None of the constituents of a thing or of an essence is an abstraction from it; each is a thing or an essence in its own right. To find abstractions we must enter the psychological sphere and consider the casual history of human ideas. A late idea, though its object may be perfectly concrete and definite, like the sphere, may be simple in comparison with some early impression – say, that of an apple – which may have first suggested it: and if the variegated essence was really distinguished first (which is not always the case) and the simple one – roundness – was only noticed afterwards as an element included in the other, then, for that person the sphere will be something abstract, not indeed in its essence, but in its mode of reaching manifestation: an act of abstraction happens first to have revealed this essence to this man. But such an approach is accidental: a true psychologist would often record that in looking at some roundish thing he first noticed and intuited nothing but roundness, perfect, Platonic, and unadulterated. The clumsiest spheroid cannot convey to an innocent mind any idea save that of a simple sphere; and our first impression of a world in which everything is crooked is that everything is straight. The enormity of our childish idealism would prove immediately fatal if we needed to have a true idea of things in order to act properly in their presence. But ideas which are ridiculous as descriptions may be adequate as signals: all animals eat and breed without any notion of caloric or eugenics: hunger and love are moral overtones quite sufficient to express for them their share in the rude economy of nature. The mind is not a fifth wheel to her coach, but her observations on the journey. Conventional psychology is misled by a primitive gnostic theory to the effect that things ought normally to appear to sense in their full and exact nature. Nothing could be further from the fact, or more incongruous with animal life and sensibility. That which appears to sense is determined at each moment by the liveliness and direction of the psyche in her current reactions. Things are thereby "known" in the sense that they are named and distinguished by their rough aspect and occasions; they are not known at all in the sense of being disclosed in their inner nature, either totally or partially. The specious essence intuited is the *name* given by the psyche to the material force encountered or exerted; it is a spontaneous symbol, not abstract even in its origin; as the word cat is not drawn out of the domestic animal, yet serves to designate it in its entirety, and is much simpler.

Repetition is impossible in the realm of essence; two essences, if not different, will be one essence; if different they will be two essences, and not repetitions of the same essence. Repetition is possible only among objects which are particular but not individual; that is, when they exist and are distinguished by their external relations, even if internally they should happen to be precisely similar, and should have but one individuality or essence. An

individual may change his relations and have different moments and places of existence, so that here he may be surrounded by one environment and there by another. This possibility of iterating or repeating an essence is what, from the point of view of existence, makes essences seem abstract or general, when in reality they are the only individuals. An essence is not the thing which it defines, and may define many things numerically distinct: what is ordinarily called one thing or one person has many separable moments of existence, between any two of which it may perish: they will be moments of one thing or one person only in so far as one individual essence pervades those moments. As nothing can be abstract in itself, so nothing can be general in it. Every essence is universal not because there are repeated manifestations of it (for there need be no manifestations at all) but because it is individuated internally by its character, not externally by its position in the flux of nature: and no essence is general for the same reason. However it may be related to particular existences, its own nature is complete and intrinsic; whereas a term can be said to be general only if it happens to be predicable of a number of scattered things, none of which, perhaps, it defines intrinsically. Yet everything that is at all must be something intrinsically: had a term no individual essence there would be no meaning in predicating it, and it could not be predicated of two things in the same sense, since it would have no sense. Before essences can be called – occasionally and in relation to natural things – either abstract or general, it is requisite that in themselves they should be concrete and individual.

The organ of intuition is an animal psyche, governed by the laws of material life, in other words, by habit: so that it is normal for intuitions to be recurrent, in so far as circumstances allow. Discourse, in which intuitions subserve intent, requires intended essences to recur identically, and imputes identity to them even when they are different, if their difference is irrelevant to the cogency of discourse, and incompatible with it. It is these intended essences, identical for intent on various occasions, but never actually intuited, that might well be called abstractions: they are like points of the compass, or limits of unending approaches, ideal in the sense of being never realized, although clearly indicated and definable by their relation to other terms which are actually given. The identity of an essence with itself is absolute and constitutional, but the identity of the essence given in one intuition with that given in another is an identity assumed and always unverifiable. It is impossible to arrest the two intuitions and compare their objects: to do this would be to supersede both by a third in which perhaps twin objects were presented: but it would remain an assumption that one twin repeated the datum of one intuition, and the other twin the datum of the other. Yet the impetuosity of life, which discourse cannot help sharing, brushes aside these scruples: habit – iteration of words, gestures, and sentiments – sufficiently identifies the essence meant at one moment with that meant at another, in contempt of the

varying context in which they may appear. This essence, not the context, is probably the only object distinctly noticed, or designated expressly. Thus the essence of straightness is continually intuited afresh, and is absolutely identical at each recurrence. It is irrelevant that the material object evoking this essence may be different in each instance, and never quite straight: that context, even if vaguely pressing on the psyche, remains unsynthesized, unnoticed, and unintended. When on looking at a palm tree, a Roman road, or the horizon, I say to myself, how straight! I have exactly the same clear feeling: and this pure essence, not its irrelevant context, is what actually fills my mind, and is the essence apprehended. All the concomitant stuff, if it were noticed in turn, would merely supply other essences of the same universality. It is impossible that anything should appear which is not universal: for it is definite and might evidently appear again. Hence the possibility of discourse: its terms are coined into fixed values, and can pass from mind to mind, retaining their original meaning.

But mind is not a subject congenial to psychologists: they would like it either to reproduce material facts or to take its place among them, or even to swallow them up and be another name for them. Since the edges of material things are known to be broken and warped in fact, it is presumed that we must actually see all lines curved or broken. But mind is intrinsically and initially mind: it is poetical and Platonic from the beginning; and it is only by a painful eventual reinspection that it can correct its first impressions and allow that material things have in fact forms too complicated for the eye to trace, and a substance too remote in its pregnant texture from the scale of sense to be easily imagined, or to be imaginable by man at all. All this subterranean obscurity, however, is in its place: a wise man will not repine at it. Where clearness belongs, clearness enough may be found: the essences actually defined by attention are plain, brilliant, and homely, like the words of the vernacular. The psyche, a plodding beast, needs but to fall into her old paces for the old visions to reappear. It is essences, not things, that are on the human scale – not all essences, of course, but those which the mind evokes spontaneously: whereas things, if humanized at all, can be humanized only by a long architectural labor – a labor which their insidious lapse very soon defeats and annuls.

That essences, though universals, are individual and are given bodily in intuition, may be better understood if we consider those existing things which are supposed to be concrete in contrast to essences. Their existence, we shall find, depends on their external relations, on their inclusion in the flux of nature; and science, in proportion as it penetrates to their dynamic structure and movement, becomes more and more mathematical, that is, operates with categories and terms more and more remote from pictorial physics. It is only when some portion of this inconceivably rapid and complicated flux of matter becomes recognizable and traceable in some respect that a

somewhat concrete thing can be found to exist. In other words, the concreteness of things is borrowed from the presence in them of some essence supposed to be abstract. Only when the flux, by its concentrations and sustained rhythms, manifests for a while locally some recognizable identity of form, can we speak of a concretion in existence, that is, of a thing. Abandon that essence, and that thing has dissolved. Certainly this essence, if it is to qualify existence, must be manifested or embodied in some nexus of events, amid variable external relations; but the flux of events itself would be the most empty of unrealities if it still pretended to flow after having obliterated within itself all distinctions of quality, direction, or phase – that is, all self-identical essences. Essences are definite and thinkable: existence is indefinite and only endured. That is the Platonic experience which I cannot help repeating and confirming at every turn; only that by "thinkable" we must not understand definable in words, but open to intuition in the terms of any sense or of any logic. The flux flows by flowing through essences; and essences are manifested as the flux of matter or of attention picks them up and drops them.

An essence, then, is no abstraction, no unrealizable generality, but any actual aspect which anything can wear, determining its nature, or revealing it to an attentive mind. The sweetness I may taste is not dependent in the order of knowledge or of being upon abstraction from anything else. In my experience it is very likely the first indication I have of any substance called sugar existing near me, to be appropriated or investigated further. When I have gathered all I can learn about sugar, the sweetness originally tasted cannot become an abstraction from this much more remote and hypothetical object. It remains a self-sufficient essence, perhaps the only one given at the moment; but its appearance has now become, for my discursive thinking and belief, a symptom of certain chemical facts in the posited material world which I believe myself to inhabit.

Objects, whether essences or facts, may be considered recurrently, on separate occasions and by separate minds: otherwise discourse and experience could have no sanity, and could accumulate knowledge on no subject. On each occasion, however, the intuition, sensation, or thought turned upon that object is a fresh event, not only numerically but almost certainly by virtue of variations in its quality, context, and mental fringe; so that the living feeling or experience of the moment is something in flux, unseizable, not recoverable, and never, even when it existed, brought under the unity of apperception. Experience is something that just because it exists (without rising to the actuality of spirit) never exists all at once as a unit but only by virtue of its parts, its movement, and its stress. Its parts exist, as it does itself, by occurring in a system of changes and conjunctions never given in such fleeting intuitions as it may include, and probably never given in intuition at all, even in the most accurate retrospect; because these moving clouds of sensibility and intent – the waking dreams of the psyche – are not objects which human attention is

fitted or required to apprehend; they are complexes of no stability or importance as units; nothing matters in them save the objects discerned by them, or discerned by us afterwards as the goals of their movement. In discerning any of these objects, whether they be essences or things, animal life becomes intuition, the synthesis of attention by which an essence appears; but this intellectual act is wholly focussed on its object and unified only there. Taken as tension or potential perception, sensibility is diffused through indefinite time and through many vital functions; it would never exist actually and become a sensation unless it became the sensation of something; the intuition of some essence, like a pain or a sound.

An essence is, then, not at all a mental state, a sensation, perception, or living thought; it is not an "idea," as this word is understood in British philosophy. It is an "idea" only in the Platonic or graphic sense of being a theme open to consideration. Mental facts are not units either in nature or in logic; they are subdivisions made by literary psychologists in the flux of experience considered romantically, as a biography abstracted from its organs and from its natural setting. The dream of life exists: it is going on perpetually in each of us; but its parts, called feelings and thoughts, are individuated only by the essences they discern, which are not the essences of those feelings or thoughts taken existentially, as moments in a dream, but are the essences of anything and everything under heaven or over it. If I think of God, the essence before me, my passing notion of the divine nature, individuates that thought of mine, and makes it possible for discourse afterwards to attribute it to me; but my thought was not God as it conceived God; it was a wretched mixture of words, memories, and dialectical groupings in my heated brain. So far is an existing idea from being the essence which it conceives.

If a romantic psychologist ever succeeded in reconstructing a moment of mental life exactly as it existed, he would be reconstructing (in the fresh setting of his own thoughts) an event itself perfectly particular and never destined to recur. But evidently, since his reconstruction is accurate, the essence given in that past moment is given again to him now; and it must recur in so far as any historian afterwards conceives that experience truly. The repetition of events is impossible; the recovery of essences is easy. Many a dead man, for instance, has considered the dyad in the form of twins, two shillings, or the numeral 2; and twins, two shillings, and the numeral 2 are still found in the world. This dyad, though I give it a learned name, is, indeed, the burden of a primitive intuition. The cat has it when she misses one of her two kittens, and the foreigner conveys it by holding up two fingers: it is not the fingers or the absent kitten that then absorb attention, but the instantly felt difference between one and two. In the midst of various vague and unsteady fields of experience quick intuition continually recovers this important primary essence. Hugging it, the mind can fly from world to world, and can make something definite and concrete out of their chaos, in so far as the dyad finds application there.

Animals live huddled among things and necessarily watchful of them, except in those hours of stolid composure in which they seem to be contemptuously availing themselves of the chance not to think; whenever they think, however, whether in dreams or in action, they can think only in terms of essences: and hence that fundamental illusion, that hypostasis of given essences, which the philosopher should regard as normal and amiable, while avoiding it in his own person as far as possible. He will succeed in this self-discipline in proportion as his interests are intellectual and set on essences rather than on things; he will then feel the sharp contrast between the clear hypothetical pictures in his thoughts and the dark complexities of nature: he will be constantly aware of being an impressionist in physics, a dramatist in psychology, a novelist in history, and a pure dialectician in mathematics. But other philosophers are not lacking to defend the illusion which animal faith imposes on everybody until criticism comes to distinguish the sphere of action from the language in which imagination expresses its adventures there. When intuition remains closely attached to urgent action – in hunting, for instance, or in pain – the essences appearing seem actually to inhabit the material object or the bodily member into which perception projects them. Given essences then seem to be constituents of substances, even when they are descriptive of perfectly immaterial facts, like intentions and feelings: such sentiments, as imagined by the observer, are boldly attributed to other people, and thought of as agencies at work within them. This dramatic sort of hypostasis is after all the most defensible, because if the observer and the observed are similar creatures in similar circumstances, they will really be having similar intuitions; so that our wild shot will hit the bull's eye by a pre-established harmony. The transcript of nature in discourse will, of course, remain poetical, since a man's sentiments are but unrhymed poems which nature improvises within him; but one poet may truly understand and repeat another.

It is harder to conceive how the form of a hollow sphere and the color blue can help to compose the substance of aerial space, or where exactly they shall be deputed to lodge: nor is it clears how these essences can occupy some nearer locus, such as a nerve or a brain. It will not help to call these appearances qualities of things, rather than parts, if the qualities are supposed to be intrinsic: the intrinsic qualities of a thing compose its essence, and its essence, when caught in external relations, is the thing itself. If on the contrary by calling appearances qualities rather than parts of things, it be meant that these qualities are adventitious and relative, the contention is valid; because any aspect, effect, or relation accruing to a thing justifies a new epithet being assigned to it, as on my birth a whole series of dead men, up to Adam, suddenly became my ancestors. So when a human eye is turned skyward, the sky truly acquires the quality of looking blue and round: those are its real qualities in relation to such an observer, as certain substances are truly poison for rats.

These ulterior questions, however, cannot arrest the impetuous dogmatic instinct which asserts things to be what they seem and to exist in the very terms in which they appear. The stones would laugh, if they got wind of this human assurance; but meantime it is not useless in developing human acquaintance with essences: because this incongruous dignity attributed to them, of being material things, has the merit of attaching practical minds to them; and later, if these wise men discover their error, they may have acquired the habit of defining essences, and may find them worth cleaving to for their own sake.

PSYCHOLOGICAL APPROACHES TO TRUTH

George Santayana. "Psychological Approaches to Truth." *The Realm of Truth* (New York: Charles Scribner's Sons, 1938), chap. 4, pp. 31–38.

Even if mathematical ideas were less exactly true of the world, the mere possession of them would be indirect evidence that they had some cognitive value and were in some way true. If we would show them to be false, we must propose other ideas on the same subject which shall seem truer. But what ideas, truer than those of mathematical physics, can we propose on the subject of the field of action or the dynamic world? Undoubtedly, if reality were confined to spiritual being, mathematics would be useless, and the study of it an idle pastime, if not a vice; and if any spiritual man, like Pascal, got too deeply entangled in mathematics, the sad effects might be seen in his self-torture and desperation. A faith founded on logic is an acrobatic and insane faith. It was not logical necessity, but hard practical evidence, that first suggested mathematical ideas to the mind and afterwards confirmed and imposed them. Animal faith honors mathematical science – a fantastic construction in itself – for measuring reliably the footsteps of that stealthy material power that pervades the world. If mathematics measures these footsteps perfectly, mathematics is perfectly true. The reality of psychologists – subjective presence, whether sensuous or conceptual – belongs to a different moral or aesthetic sphere, not mediated by animal faith and not itself conveying knowledge of truth, true as the account of such experience may be which is conveyed later by memory or sympathetic fancy: for often the art of fiction may tell us the truth about the fictions natural to the mind.

Nevertheless, intuition, which is simply sensibility focused and actually noticing anything, comes upon essences, not things: because in proportion as attention takes notice, and honestly observes what it finds, it suspends that animal faith which was involved in fear or care or the physical impulse to react upon some physical stimulus. When clarified and thoroughly actualized, all data are essences: if the spirit could actualize and clarify everything it would live altogether in its congenial ideal world, as it does, with some lingering qualifications, in mathematics and poetry and music. But in animal life this remains an interlude, something marginal and ulterior. Living attention comes upon essences with a bias, from some particular vital angle: they are stepping-stones in a distracted career. Even if clearly focused in their own

plane, essences do not dictate to us in what direction their relations shall be traced: in themselves they have no movement, no selectiveness, no propulsion. The choice of this or that path, in further intuition, is made by the animal mind, under suasion of casual interests or its own vegetative growth. Poetry does not make itself, poets must make it: and so mathematicians must make mathematics. Narrow paths are thus opened by accident through the compact thicket of essential Being; and later comers, threading the beaten way, may suppose that they are surveying the whole structure of the labyrinth, and discovering the eternal Logos, or self-chosen necessary truth. But the labyrinth, being infinite, offers all choices to the wanderer; and the pattern actually traced was selected by accident.

Logic is a refined form of grammar. If in my prattle I obey a tendency, and later establish a rule to the effect that nouns shall be either masculine or feminine; and if I obey a tendency and make it a rule that adjectives shall match and prolong the gender of their substantives; *then* it is requisite for propriety of speech that adjectives and nouns should possess gender, and should march in couples, like clerical school children, the girls with girls, and the boys with boys. And this contrast, with this divided way of trooping together, artificial as it is in things without sex, opens the way to the most charming assonances and beckoning of word to word in discourse, enabling us without confusion to pick our way through a minuet of cross-references, as in an ode of Horace. Yet grammar need never have adopted so fantastic a sexual analogy. It did so only because speech is radically expletive, redundant, and exclamatory, as thought is also; and in a creature to whom sexual images are arresting and highly provocative, sexual analogies, however farfetched, will appear in all sorts of places, particularly when emotion is aroused, and will count for more in the play of description than does the strict truth of the object.

There are other graver intrusions of the grammatical medium into the deliverance of thought. For instance, the relation of subject to predicate is founded on the circumstance that some words are proper names, and merely demonstrative, like a pointing finger; other words are names of essences, without traceable physical being, but appearing dispersed, repeated, and mysteriously intermittent in all sorts of places or in no place at all, that is to say, in the mind. The proper name, indicating and holding down, as it were, the physical object that concerns us in action, becomes the grammatical subject; and the names of such essences as this subject shares with other things become grammatical predicates and adjectives. This grammar registers admirably the education of the mind: for the mind is commonly awakened by some shock, and then proceeds more or less scrupulously to describe the circumstances and the qualities connected with that stimulus.

Moreover, being a spirit beset by animal obsessions, the human mind can retain, compare, and synthesize its impressions, leaving the flux of existence

to run on as full and turbid as it will. Yet this recollection and this withdrawal are always imperfect. The basis of spirit is itself material, fluid, and self-forgetful: while on the other hand, the knowledge gathered and the pictures painted by the mind are simplified unduly, conventionalized, moralized, reduced to types: and this does violence to the truth, since nature is not human education hypostatized. Hence the quarrel between the humanities and science; in which science evidently represents the interests of truth. If the problem were scientific, we should have to consider that science also is human, that neither in texture nor in scope can science be identified with the truth: and that the humanities too convey poetical information about historical matters. But the real problem is moral; and even if science presented the truth more honestly than the humanities, we should still have to ask whether these scientific truths were the most important, and even whether the knowledge of truth is the ultimate goal or good of mind. Frankly, it is not, when the mind is free. Spirit is the entelechy or ultimate fruit of life and not a material instrument or means to action; and if once life were safely adjusted and directed amid material circumstances, consciousness of those circumstances would be superfluous except as it might be interesting; so that truth would take its place side by side with fiction of every sort, to be valued not because true – for merely being true does not make things worth knowing – but only for invigorating and entertaining the mind. Such is the liberal life; and the humanities have this liberal character, although science also has it, in so far as the truth of it enlarges the imagination. But such poetic freedom in thinking is premature, and even criminal, when the psyche is living at cross-purposes with the possibilities of life. Health must be established first and organized securely; and then the range and balance of spiritual interests may be left for free genius to determine.

In any case, it would be a vain scruple in the lover of truth to quarrel with his intellect and with the grammar of his thoughts in order to put his ear closer to the ground. His ear is itself an animal organ, and its deliverance – sound – is the substance of nothing except music. The tread of oncoming reality may be conveyed more impressively or more accurately by one sense than by another: but in the end only intellect and science will be able to reveal the method of that approaching attack, or the method of meeting it by any deliberate or artificial contrivance. There is no ground for deprecating this intervention of art and reason. Mind is better than matter in the estimation of mind: and this judgment is final, because only mind is capable of esteeming or judging at all. Attention to matter is therefore optional for a moral being, and important only when, health having been lost, art is requisite for recovering it; or when, as I was saying just now, attention to matter is spontaneous and self-rewarding, as it is for children and for the true naturalist. The office of matter is precisely to breed mind and to feed it; and while the fantastic egotistical errors into which mind may fall, since it must conceive matter in

terms of ideas, might seem laughable to omniscience, those errors do no harm to matter and very little to mind. An unbiased and literal understanding of matter would be incongruous in an animal; and for pure spirit such understanding remains an ulterior speculative ambition, legitimate certainly, since spirit is potentially omniscient, but rather beside the mark when, being incarnate, that spirit is beset by impurities which it must purge first, before it can ever understand anything or know itself. If it knew itself, spirit would be little pressed to understand the depths of matter, which cannot be changed; but spirit, by existing, does lend to matter a new mental dimension, expressing material organization morally and perhaps gloriously. Better than idly mirroring nature in mind (if it were possible to do so) is to impose an ideal measure upon fluid things, and this not arbitrarily or insignificantly: for the very dependence of spirit, which might seem to condemn it to futility, renders it an index to deeper realities and an organ of truth. Thought would never arise or maintain itself, it would never succeed in imposing formal measures and unities on events, if these events, which include the biological organs of thought, were not already organized and self-distinguished in the bosom of chaos. The very existence of fiction endows fiction with a native relevance to truth.

We are told by certain psychologists that although the dynamic order of events is not *really* mathematical, mathematical fictions must be cultivated because they are *useful in the practical arts*. But why should they be useful if false? And how should they be false if they describe the efficacious order of nature, by which our existence and health and power of speech and thought are notoriously controlled? What better criterions have we of truth than pertinence to action and implication in the dynamic order of nature? Primitive imagination no doubt attributes power to wishes and prayers or to formal rhymes and coincidences in the aspects of things; but that is superstition; and we gradually discover the true order of nature by attentive observation of matter, and experiments with it, and calculation of its quantity and movement. If arithmetical and geometrical notions gain such ascendancy over the expert mind, it is precisely because, in their abstraction, they are the surest measure of the concrete. By them we retrace the actual vectors of reality and energy in the living world. What the vitalists call life is, in comparison, but the after-taste and rhetoric of motion.

Irrelevant, then, as the inner cogency of logic may be to the truth, logic nevertheless possesses a natural truth in its first notions, in its chief lines of deduction, and in many of its development. Such applicability rewards later speculation for the early diligence of mankind in studying material things, turning and molding them, and making their image precise in thought. Ideas are not true because they are clear, but often they have become clear because they were true. This truth gives continual encouragement to the dialectician in tracing his deductions and trusting his insights. Yet he goes too far when

with these ideas, framed on the human scale and true and empirically tested on that scale, he presumes to fathom the depths of matter and of time, and to dictate to nature the mechanism of her motions. He ought rather to expect that in some dimensions of being, for instance, in the mind, or at a high degree of complication, as in living bodies, the applicability of his ideal science should cease to be perfect or should fail altogether. Not that in those regions there is less order than in the gross mechanical world: there is evidently more, and a more organic order: but our images and thoughts are not easily adapted to those latitudes and longitudes, and the most signal instances of responsiveness in events seem to us miracles or accidents.

Such limitations are not at fault in human logic or mathematics, as if mankind had been bewitched and ought to begin thinking with other images and other axioms. Even if such a reform of the intellect were possible, and fresh ideal systems were developed, expressly to fit the regions newly explored, the new logic and mathematics would not be likely to fit all reality, or to possess more than a limited and borrowed truth. Nature, we must never forget, is in flux. This flux may move in any number of streams, according to any variety of methods; and even if, at one time, we had obtained an exact formula for everything, presently the flux might take a new turn, and insensibly change its fluid constitution. Then the very accuracy of our earlier measures would render them worthless in a later world.

Section Two

Evaluations of Santayana on Pragmatism

REVIEW OF *THE LIFE OF REASON*

Addison W. Moore. "Review of George Santayana, *The Life of Reason*, vols. 1–4." *Journal of Philosophy, Psychology and Scientific Methods* 3.8 (12 April 1906): 211–221.

George Santayana. *The Life of Reason or The Phases of Human Progress*. New York: Charles Scribner's Sons, 1905. Vol. I., *Reason in Common Sense*, pp. ix + 291. Vol. II., *Reason in Society*, pp. ix + 205. Vol. III., *Reason in Religion*, pp. ix + 279. Vol. IV., *Reason in Art*, pp. ix + 230.

In the addresses delivered last year at the many memorial celebrations of the late Herbert Spencer's life and work, there was one very common theme: it was the anachronism of such an encyclopedic program as Spencer attempted – an anachronism which even the Hegelians of Spencer's day discovered in the similar ambition of their master, and one, it was said, which Spencer would have avoided had he possessed a larger historical knowledge and appreciation. And it was freely predicted that Spencer's attempt would be the last of the kind to be seen for many generations.

In the face of the extended currency of such comment among philosophers, to say nothing of the cynical attitude of scientists, it must be as significant as it is interesting that one who can not be suspected of any lack of large historical orientation – one, indeed, whose method is historical – deliberately, 'with malice aforethought', sends through the press within a year a volume of what may be called first principles, a philosophy of society, a philosophy of religion, a philosophy of art and a philosophy of science.

To be sure, we are in the midst of a great revival of metaphysical interest. But the products of this revival thus far, as presented in the works of Mr. Bradley, Professor Royce, Professor Fullerton and Professor Taylor, have been in the main of the systematic formal type inevitable in abstract metaphysics. Professor Santayana's work, however, is of a different character. He is interested in tracing the effect of the method upon the content. He is concerned in showing the connection between the general conceptions of reality, truth and goodness and their conditions and effects in society, religion, art and science. In his own sentences, "The problem is to unite a trustworthy conception of the conditions under which man lives with an adequate conception of his interest"; again, "Starting with the immediate flux in which all objects and impulses are given, to describe the life of reason; that is, to note

what facts and purposes seem to be primary, to show how the conception of nature and life gathers around them, and to point to the ideals of thought and action which are approached by the gradual mastering of experience by reason" (I., p. 32).

And Professor Santayana is fully aware of the proportions of his task. He hastens to nip in the bud any suspicion of quixotism by saying that such a program "would be beyond the powers of a writer in this age, either to execute or conceive, had not the Greeks drawn for us the outlines of an ideal culture at a time when life was simpler than at present and individual intelligence more resolute and free."

In general, of course, Professor Santayana's courageous attempt, as all others, must be justified by its fruits. But I can imagine it quite possible for him to say that such an attempt is not only justified but necessitated in advance by his very conception of the place of reason in experience. An inkling of this appears in the subtitle itself, the whole caption being "The Life of Reason, or the Phases of Human Progress." The implication is that the character and function of thought is to be discovered not by isolating it and attempting an analysis of it as 'pure' reason, but by observing reason at work in the world, catching it in the act, taking it in its context in the whole concrete stream of experience. The attempt to discover the nature of reason apart from its products leads to a monstrous misconception of it and the proposal to substitute this changeling for normal reason, for reason as it is in operation, is called "visionary insolence." "Retrospective self-consciousness is dearly bought if it inhibits the intellect and embarrasses the inferences which in its spontaneous operation it has known perfectly how to make" (I., p. 29). If, then, the nature of reason is to be discovered only by observing it at work in science, in religion, in art and in social organization, is it, after all, presumptuous to propose to describe the processes, the phenomena and the results in which the nature of reason, even for one proposing to give the most abstract account of it, must be revealed?

What, then, is the life of reason, or, conversely, what is the rôle of reason in life? The reviewer has to confess that in the end the answer does not appear so univocal as the introduction promises. The problem centers in the relation of reflection to impulse. In other words, in the sort of 'efficacy' ideals have. In the introduction ideals, ends, constructed in reflection, are apparently regarded as actually organizing the material of habit and instinct. Here reason is defined as "efficacious reflection." And the 'efficacy' here consists not merely in an 'added content' which it brings, but in the added *function* of control. Hence we read, "To the ideal function of envisaging the absent, memory and reflection will add ... the practical function of modifying the future. Vital impulse, however, when it is *modified by* reflection and *veers* in sympathy with judgments pronounced on the past, is properly called reason" (I., p. 2). "The life of reason will, then, be a name for that part of experience

which perceives and pursues ideals, all conduct *so controlled,* and all sense so interpreted as to perfect natural happiness" (p. 3). Again, "In the life of reason, as it were brought to perfection, intelligence would be the universal *method of practise* and its continual reward. All reflection would then be *applicable in action* and all actions fruitful in happiness" (p. 5, italics mine). Here we are very properly warned that this controlling, instrumental character of thought does not make it a mere means. It does not prevent its having an immediate value of its own. But though reason may in this sense be "its own excuse for being," yet in order to *be,* it must *do*; and its 'doing' is just the work of converting isolated impulses and instincts into a mutually stimulating and checking, *i.e.*, controlled, system.

But when we reach the chapter on "How Thought is Practical," one is puzzled to find thought losing this character of control and becoming a mere 'expression', 'effect', 'register', 'celebration' of 'mechanical', 'material' activity, into which now all dynamic efficacy is transferred. We now read, "Thought is nature's concomitant expression or entelechy, never one of her instruments" (I., p. 223). "Consciousness itself is not dynamic.... It is merely an abstract name for the actuality of its random objects. All force, implication or direction inhere in the constitution of specific objects" (I., p. 220). "Preferences are in themselves, if the dynamic order alone be considered, works of supererogation, expressing force but not producing it, like a statue of Hercules" (p. 221). Yet near the close of this puzzling chapter we read that the function of thought is "to lend utility to its causes" (p. 233), which here are material. "It is potential energy *producing* life and becoming an actual appearance." Again, in Chapter XI., on "Conditions of the Ideal," "Reason and the ideal are not active forces, nor embodiment of passion at all" (p. 265). Yet on the same page, "This suggested peace (for the conflict of impulses) ... is the ideal which *borrows its practical force* from the irrational impulses which it embodies" (italics mine).

It may be said that the mere appearance of a 'sense of value' in a process 'bestows utility', simply by giving the process a limit, a *terminus ad quem*. But even so this involves some sort of reaction of this 'sense of value' upon the mechanism, otherwise why should the process not simply go on grinding out 'senses of value', without using them as limits? It is Aristotle's problem of the unmoved mover. This discrepancy, as it appears to the reviewer, can be charged to an oversight of the distinction between consciousness in general and reflective, cognitive consciousness. 'Consciousness', 'thought', 'mind', 'reason', are freely interchanged throughout the chapter. Recognizing that the 'sense of value' belongs to consciousness-mind, it is apparently inferred that this is *all* that belongs to it and that all dynamic efficacy must therefore be referred to material nature, of which thought is the mere 'symbol', and which even "can hardly lie in the same plane of reality with the thought to which it appears" (p. 219). Value is obviously a category of conscious activity, and as

immediate 'content' is perhaps not dynamic. But is it not just the business of reflection to convert this '*sense* of value' into an ideal, an end? And as an ideal it surely must be regarded as dynamic in the sense of being an essential factor in a system conceived as 'dynamic'.

In its more general form this question which divides the first and the last four chapters of Volume I. is, How can the ideal be both an 'expression' and a reconstruction of instinct and habit? How can it arise out of and yet be the standard for impulse? In logic it would be the old problem of universals. Now one of Professor Santayana's theses, – indeed, one might say, the fundamental one, – is that the ideal, whether in government, religion, ethics or art, must grow out of, must be an 'expression' of, impulse. The clearness and force of his exposition of the vanity of an absolute ideal given to the impulses from without could not be surpassed. "Demands could not be misdirected, goods could not be false, if the standard by which they are to be corrected were not constructed out of them" (p. 258). Again, "Whence fetch this seminal force and creative ideal? It must evidently lie already in the matter it is to organize. Otherwise it would have no affinity to that matter, no power over it, and no ideality or value in respect to the existences whose standard and goal it is to be" (III., p. 88). The ideal, then, must be an expression of the matter, in order that it may have enough 'affinity' with it to organize it; this despite what is said above about thought not lying in the same plane with its material.

Corresponding to these two conceptions of the ideal, the one as an 'expression', the other as control, there are two conceptions of the 'matter' to be organized. Where the controlling, organizing character of the ideal is emphasized, as in the introduction and in Volume III., impulse, instinct, immediate flux, etc., constitute the 'matter'. But where the ideal is expounded as an 'expression' of impulse, the matter appears as 'physical', as 'body', in opposition to consciousness and as the latter's 'cause', – and this, too, apparently in quite an ontological Cartesian sense. Indeed, the whole treatment of the distinction of mind and body is to the reviewer as equivocal as that of reflection. Sometimes the distinction appears to be a rational construction within a process of experience which can not be described as either or merely both (*e.g.*, I., pp. 39, 234). But again, and perhaps oftener, 'matter' appears as an existential *prius*, as "the antecedent of human life" (II., p. 200) to which somehow "mind accrues."

The present writer is well aware of the enormous capacity of reviewers' quotations for misrepresentation. He is also aware that there are many passages which could be cited to show that what has been described as different and discrepant conceptions of reason and its place in experience, are simply two supplementary phases of one conception, namely, that reason is *both* an 'expression' and a control, and must be the one in order to be the other. However, the reviewer can only record his impression of ambiguity in the account as it stands.

To many such captious, logic-chopping criticism as this may appear *mal apropos* in a review of a work whose style makes the reader feel much of the time as if he were following a brilliant impressionistic commentary on 'phases of human progress', rather than a systematic treatise. But Volume I. is obviously intended as an exposition of general principles, and must therefore, be held to the canons of systematic criticism.

Passing to the treatment of reason in society, religion and art, we find that the indigenous relation of the ideal to impulse so forcibly, if not altogether consistently, expounded in the first volume, is the nerve of the doctrine of these volumes. The history of these aspects of human progress is the story of the reciprocal creation and maintenance of impulse and reflection which constitute the process of human life. Accounts of its defeats are invariably descriptions of the failure to maintain an organic relation of these factors, of attempts to appropriate a readymade ideal in either an absolute or an anachronous historical form.

Thus the ideal side of love does not merely 'add' a larger and more permanent value to the instinctive side, but it constitutes the salvation of the instincts. It is the method whereby any instinctive expression of love can be 'converted' in order to be saved under the new conditions which its own previous activity has created. Instinctive love, therefore, must be reformed in order to survive. This does not mean that it becomes less instinctive. It means only that the instinct shall emerge enriched in quality and extent of its content. When the need of conversion, of idealization is unrecognized, or unheeded, or when the conversion is attempted through extrinsic ideals of another race or clime, or when it becomes virtual annihilation, then all sorts of 'perversions' occur.

Obviously one of the results of immediate, instinctive love, which calls for expansive reconstruction, is the presence of offspring. The family is the ideal construction through which the reproductive impulse is expanded into interest in the protection and development of life. But just because it is thus necessarily one of the earliest organizations of impulse, "it becomes a point of departure for many other institutions." And "it often assumes offices which might have been allotted to some other agency had not the family preempted them." The annexing of these "adventitious, parasitic functions" to the family so overloaded it that it did none of them well. With more stable occupation of land, the reverse process of unloading these functions on new institutions begins.

Here we face again the perennial problem of balance. On the one hand, the refusal to surrender old prerogatives in the face of a new world, or the attempt to conduct the new family by the rules of the old, leads inevitably to dualism and disintegration. This is a problem for experience to solve. It can not be solved in a Utopia. The statesman in his sphere and the individual in his must find as they go the best practical solution. On the other hand, this

unloading upon other institutions, as the school, church, the factory, etc., may go on until the family may be emptied of almost everything but the reproductive function, – bringing up again the problem of maintaining the control and value of the latter. This, perhaps, may be effected by the reaction of these emigrated functions "in stimulating a larger social, philosophical, scientific and artistic interest."

In view of what precedes, one is somewhat surprised at the beginning of the discussion of government to find it identified with "what in physics is inertia, in psychology habit." "In society it (habit) takes the form of custom, which, when codified in law and when enforced, is government. Government is the political representation of a natural equilibrium of custom, inertia; it is by no means a representative of reason" (II., p. 70). But, the reader may ask, if custom were really effective as a custom, why codify it? And what need to enforce it if it is already enforced as a habit? Codification surely is a process of *re*construction, therefore of idealization. And this is really implied in statements which immediately follow. "But like any mechanical complication it (government) may become rational.... Government can by its existence define the commonwealth it tends to preserve." But if it is government through codification, the 'can' should be 'must'.

This is also implied in an interesting and suggestive discussion of the various forms of government which follows. The problem is presented as just that of the best method of constructing and presenting a social ideal. The answer, as Aristotle saw, depends upon the specific conditions. "All just government pursues the general good. The choice between aristocratic and democratic forms touches only the means to that end. One arrangement may well be better fitted to one place and time than another" (II., p. 121). Where there is stratified stagnation, some form of aristocracy, theocracy, monarchy or oligarchy may be the best means to get reconstructive idealization started. However, history seems to warrant the claim of democracy that these forms of aristocracy "have been unable to remain representative." But the inferences which democratic theory often draws, that "eminence is therefore not representative, and that representative character is bestowed by the mechanical expedient of universal suffrage," do not follow.

Many stimulating things are said in the discussion of the distinction between 'political' and 'social' democracy. Political democracy is "a symbolic extension of aristocratic privileges in the form of universal suffrage." "It is quite compatible with complex government, great empire, and may retain, as in England, many vestiges of aristocratic institutions" (II., p. 115). Social democracy, on the other hand, "is a general ethical ideal looking to human equality and brotherhood." "It is the democracy of Arcadia, Switzerland and the American pioneers." Instead of measuring our

prosperity by the quantity of wealth produced, as our present system of economy does, it decries this enormous production, demands less labor, a simpler and more rural life. "It would abandon the great cities to ruin, as seats of Babylonian servitude and folly, leaving the railway bridges to collapse, the tunnels to choke and the hulks of steamers to rust in the harbors." In the present high tide of commercialism such anticipations may seem fantastic. "But does any thoughtful man suppose that this commercial tendency will be eternal or that the present experiment in civilization is the last the world will see?" (II., p. 127). If social democracy would take a more liberal form and permit the benefits of civilization to be integrated in eminent men, whose influence should direct and temper the general life, it would become a timocracy and would, in the author's opinion, "unite the advantages of all forms of government and avoid their respective abuses" (II., pp. 128, 129).

Despite the fact that some readers are sure to renew the complaint of dualism in the character of the relation between the ideal and its material, they may possibly find the author's brilliant power of analogical analysis at its best in the volume on religion. "Another world to live in, whether we expect ever to pass wholly into it, is what we mean by having a religion" (III., p. 6). What, now, is the relation of religion to the life of reason? Let us recall that the essence of reason is the construction of an ideal. And what is the 'other world' of religion but this ideal? "Religion thus exercises a function of reason" (p. 7). What, then, are the differentiae? First, religion carries over into the ideal a part of the material of experience, while in scientific reason the ideal is conscious of its formal and hypothetical character. Further, in its attempts to carry up the material, the masses of sentiment and ideas, into the ideal, it must construct its ideal through the intuitive instead of the conceptual image. Here lies both the real strength and the historical weakness of religion. The statement of the ideal in terms of the material, *i.e.*, in terms of instinctive and perceptual imagery, gives a richness and fullness to religious idealization impossible in science where idealization is more abstract. Indeed, "religion has the same original relation to life that poetry has." The only difference between poetry and religion, purged of its errors, is that "religion deals with higher and more practical themes, with sides of life which are in greater need of some imaginative touch than are those pleasant and pompous things which ordinary poetry dwells upon." Historically, however, "the religious pursuit of the life of reason has been singularly abortive." This because it has constantly confused the perceptive instinctive material which it utilizes to embody the ideal with the unidealized, that is, the actual existent material, and has accordingly often tried to usurp the work of science (II., pp. 8–13.)

Here the reader wishes the volume on science were at hand. From what is here said of science, one suspects that in science, at any rate, the ideal

constructions of reason are likely to be something more than mere 'additions' of value and 'celebrations' of work done by reflexes. Doubtless they are all this, but one gathers that in science, as in the passages above cited in Volume I., the ideal controls as well as 'celebrates'; that the distinction between 'efficient' and 'final' cause is likely to break down.[1]

The fact that ideal construction in religion, as elsewhere, must, on the one hand, be loyal to the impulses out of which and for the sake of which it arises, and yet can only be loyal by 'remodeling' them, determines the two fundamental phases of religious experience – 'piety' and 'spirituality'. Piety is "man's reverent attachment to the sources of his being and the steadying of his life by that attachment" (III., p. 179). "It drinks at the deep elemental sources of power and order. It studies nature, honors the past, appropriates and continues its mission." Spirituality is the creative or rather recreative function of the ideal. Piety is retrospective. Spirituality has its face toward the future, while piety dwells in the realms of established order. Spirituality pitches its tent out on the frontier, not in order to gain a worldly advantage over piety, – for "competitive worldliness is the most deadly foe of spirituality," – but it abides there by virtue of the demands of its free recreative work. By that same token is its habitation also on the borders of mysticism. Mysticism arises out of the element of failure in the work of recreation. It serves to tide over a period of intellectual arrest until there is recuperation sufficient for the work of reconstruction to again become articulate.

Maintenance of spirituality therefore depends upon a proper balance between impulses and ideal. Hence a too rapid differentiation, multiplication of impulses, or a too great sophistication destroys spirituality. However, some readers may experience difficulty in following Professor Santayana to the conclusion that brute life "may be as truly spiritual as human," and that "the only pure mystics are the brutes." For, while mysticism is a renunciation of discursive reflection, the latter must after all first be there to be renounced. The neo-platonist reaches the summit of his mount of transfiguration by the tortuous path of discursive intellection. As a preparation for the ecstatic vision he must first experience the impotence and vanity of reflection.

As for individual immortality, Professor Santayana regards most of the empirical evidence as "beneath consideration." "The palpitating mood in which it is gathered and received make gullibility and fiction play a very large part in the report; for it is not to be assumed that a man, because he speaks in the first person and addresses a learned society, has lost the primordial faculty of lying" (III., p. 230). Even at their face value these reports show only more subtle and subhuman sensibilities than ordinarily appear. They would show only that the process of dying is more complicated than is supposed, rather than point to the existence of disembodied spirits. "A disembodied life

[1] The volume on science has appeared since the review went to press.

would not betray itself in specters, rumblings and spasms" (p. 234). That operations more subtle than ordinary should occur is entirely consonant with reason and experience. But "only a hankering tenderness for superstition, a failure to appreciate the function both of religion and science, can lead to reverence for such oracular gibberish as these influences provoke" (p. 233).

The moral and metaphysical grounds of individual immortality are but little less convincing to Professor Santayana than the empirical evidence. What reason is there to suppose that more justice or that better fulfillment of ideals can take place in another life than here? If there is any continuity in content and method with this life – and without such continuity nothing remains of individual existence – life elsewhere must involve the same reference of ideals to specific conditions and the same possibility of their lapsing and yielding to others more capable of execution (p. 248). Individual immortality is an hypostasis of "the vision of eternity in time." When a fact is idealized through reflection it acquires "a status in eternity." But "having a status in eternity does not mean being a part of an eternal existence petrified and congealed into something real, but motionless." It means only that "every fact in being recognized takes its place in that ideal sphere of truth which is the common and unchanging standard for all assertions" (p. 267).

In view of what is said (p. 248) concerning the basis of the ideal in "a dynamic world," and more especially concerning its relevance to "specific tendencies" and the consequent necessity of its "lapsing and yielding to others," some will question this conception of an ideal sphere of truth which is "the unchanging standard for all assertions," and wonder whether, despite the illumination which Professor Santayana turns on in his exposition of the indigenous ideal, the ghost of absolutism does not still walk in places.

Following the general plan of the entire work, between the initial chapters of definitions and principles and the closing chapters of general conclusions and applications to current problems, are a number of chapters devoted more conspicuously to historical and genetic interpretation, in which the author's unusual ability in suggestive epigrammatic generalization has large play. Many will find these the most attractive part of the volume. The reviewer would note especially the chapters on "The Christian Epic" and "The Christian Compromise."

It was to be expected that Professor Santayana's volume on art would be authoritative; and in the main this expectation is not disappointed. Especially is this true of the chapters presenting the specific contents of art – 'music', 'poetry and prose', etc.; and of the chapters on "The Justification of Art" and "The Criterion of Taste."

In its largest sense, art is simple, practical reason or reasoned practise. "It is plastic instinct, conscious of its aim" (IV., p. 4). But here again we encounter the issue between the epiphenomenal and the instrumental character of consciousness; and again the outcome seems ambiguous. On the one hand,

this consciousness of aim 'simply accompanies' instinct (p. 5). It is not an instrument of control. It is a mere 'expression'. "Only by virtue of a false perspective do ideas seem to govern action" (p. 6). "All invention is automatic, ideas come of themselves, dropping in their sudden form from the blue" (p. 7). "All useful things have been discovered as the Lilliputians discovered roast pig" (p. 10). On the other hand, "art is reason propagating itself" (p. 13) and "reason with the order in every region it imposes on life is grounded on an animal nature and has no other function than to *serve* the same" (p. 191, italics mine). Also we read of objects of art as "things which would not only have *betrayed* the agent's habits, but would have *served* and expressed his intent" (p. 4). This seems to make overt action the expression of the intent, instead of the converse.

In view of the remarks already made on this issue in the discussion of Volume I., we must leave it here with these observations: (1) Of course, from the standpoint of experience regarded as a whole, all activity within it, whether viewed as conscious or unconscious, must be 'automatic', in the sense of being self-active. From this standpoint the operation of ideas is as 'automatic' as that of the heart or lungs. But (2) this does not prevent ideas being 'instrumental' from exercising real control, any more than the automatic action of the heart and lungs destroys their interaction. One stage of activity may condition another without either becoming thereby less 'spontaneous' in its immediate activity. (3) On Professor Santayana's own most excellent showing, ideas can not quite 'drop from the blue'. They must 'express', 'grow out of', be 'relevant to' some instinct or set of instincts. While, in the stock instance, the forgotten name 'just comes' when it does come, yet it would not come even 'in its sudden form' were it not for the want and for the agonizing effort which precedes, fruitless as the latter may appear at the time.

But, after all, this binomial conception of the general relation of art to reason does not seriously affect the rest of the treatment. For in such a case it is always possible when danger threatens from one side to pass instinctively to the other.

Resuming then the account of art in general as activity mediated by an aim, it is evident that contrary to much current opinion, art is not to be defined by mere correlative contrasts with industrial utility, science or morality. Nor is it to be identified with immediate esthetic valuation, which is only a prominent element in 'fine art' as distinguished from 'industrial art'. It is not a specific sort of experience, coordinate with other sorts. It is rather the concrete whole of consciously mediated life of which industry, fine art science, and morality are differentiations.

The general basis of art, then, lies in the fact that in the end an unmediated or a completely mediated activity is an impossible conception. "Activity, achievement, a passage from prospect to realization, is evidently essential to

life. If all ends were already reached and no art were requisite, life could not exist at all, much less a life of reason" (p. 28).

In art in this large sense, as the art of living, there are obviously two fundamental factors: the 'material' in the form of the structural products of past activity, which are demanding opportunity for further function; and the 'ideal' which supplies this opportunity. But once more we must beware of an ideal imposed from without. "The ideal is a concomitant emanation from the natural, and has no other possible status" (p. 28).

The organic relation between these two constituent functions of activity furnishes also the basis for the distinction between 'servile' and 'liberal', or 'fine' art. If the demand of some particular part or organ of the total structure for expression, or for maintenance, is so immediately urgent that a comprehensive organization, *i.e.*, idealization of the response, is impossible, the result is a 'servile' art in the form of the barren automatisms of savage dance and song, or a utilitarian struggle for mere existence. Liberal, or fine art, is the result of a balanced interaction between the activity of that part of the structure calling for expression and maintenance and the idealizing activities of the response. This means that the demands for expression and maintenance are themselves more ideal, less immediate in their insistence; and, on the other hand, that the ideals are more effective because they embody more material.

From this standpoint it is evident that no impassable distinction can be drawn between 'industrial' and 'fine' art. For, "Every proximate end in being attained, satisfies the mind and manifests the intent which pursued it, while every operation upon a material, even one so volatile as sound, finds that material somewhat refractory… . A certain amount of technical and instrumental labor is thus involved in every work of genius, and a certain genius in every technical success" (p. 33). In so far as the distinction is to be made, it is simply one of stages in one continuous process. The industrial stage is the one "in which untoward matter is being better prepared or impeding media are overcome." In the liberal stage, the prepared matter "is appropriated to ideal uses and endowed with a direct spiritual function" (p. 32).

After this identification of the essential elements of art with those of other rational functions, one is not surprised to find the volume closing with an eloquent arraignment of the modern separation of art from its industrial, moral, religious and social matrix. As usual, Professor Santayana's own words can not be improved, hence I quote freely. "The great obstacle which art finds in attempting to be rational is its function isolation." At present art "too much resembles an opiate or a stimulant." Our museums are "mausoleums in which a dead art heaps up its remains." "Art whose products are so collected and exhibited is gratuitous and sophisticated and the greater part of men's concern about it is affectation" (p. 209). "Art, like religion, needs to be absorbed in the life of reason.... It needs to have its processes diffused throughout all life activity, instead of being confined to abstract

productions called 'works of art'" (p. 208). At present art is symbolic and vicarious and stands in contrast with reality. But if "it were knit more closely with other rational functions, to beautify things might render them more useful, and to represent them most imaginatively might be to see them in their truth" (p. 213). Then, "No work would be called in a special sense 'a work of art', for all works would be such intrinsically. There would need to be no division of mankind into mechanical, blind workers and halfdemented poets, and no separation of useful from fine art, such as people make who have understood neither the nature nor the ultimate reward of human action. All arts would be practised together and merged in the art of life, the only one wholly useful or fine."

REVIEW OF *SCEPTICISM AND ANIMAL FAITH*

John Dewey. "Review of George Santayana, *Scepticism and Animal Faith*." *The New Republic* 35 (8 August 1923): 294–296.

Mr. Santayana has been known to readers, professional and lay, as a critical commentator of life, as a moralist in the true sense of the word. His insight and notation have been so genial and direct that some readers, professional as well as lay, have classed him as without philosophy, as without continuous logic, an utterer of aperçus, interesting to those whom they interested but without logical coherence and foundation. This view is a tribute to the art of Mr. Santayana and the consummate skill with which he kept his long logic subordinate to his vision and expression of the facts of life, of the good or happy life. Speaking of this dullsighted class of critics Josiah Royce once remarked that Mr. Santayana had a definite philosophy from which he never departed: the radical and complete separation of existence and essence.

In his new book the role of morals and metaphysics (Mr. Santayana himself uses the latter word in a different and disparaging sense) is reversed. Its theme is the separation of existence and essence, the beauty of essence and the indignity of existence. Essence is doubly beautiful; it is the subject-matter of the poet's vision; every soul that sees the world simply and candidly without the sophistication of dogma – which is much the same as without the sophistication of practical ambitions – is poetic. It is also, under Mr. Santayana's hands, a thing of beauty for the philosopher for it enables him, when it is rightly envisaged, to become a complete and thorough sceptic as to direct knowledge of existence while it also opens to him an unshakable "cognitive certitude" – the being of essences which are the only thing worth knowing. For, as the acute reader of Mr. Santayana's moral writings is aware, existence is to him inherently ridiculous, for the physical basis and origin of ideal goods (and of course essence is ideal) is comically disparate to its ideal fruits. All existence is physical or is matter, and since essence is ideal and its generation by existence is adventitious and its maintenance accidental, existence is meaningless. And what can be more comic than existence which is meaningless, aimless and mechanical, and yet is the sole author and support of the only things worth while, the ideal forms that fill consciousness? And so the moral – for Mr. Santayana cannot even as an overt dialectician wholly

cease being a moralist – is to enjoy the contemplation of essence. Moreover by perceiving and enjoying the spectacle of the total irrelevance of existence to essence, we may escape from the tragedy of existence. For tragedy has its source in expectation – in expecting existence to do something for us, in being interested, as we are interested, in meanings, goods. Thus complete scepticism as to existence saves us from expectation, which is practical, egoistic, the tragic illusion of the man who takes material affairs seriously instead of taking essences poetically. Mr. Santayana's sympathy with Greek thought has always been familiar to his readers. His present work reveals – and I think the revelation will come to others beside myself as a surprise – a congeniality with Indian Brahman thought: the insignificant character of the whole world of existence.

As Mr. Santayana is aware there are points in his doctrine that are dangerously similar to types of philosophy for which he has only abhorrence. One of the most illuminatingly direct chapters – and Mr. Santayana's discourse is much less direct than his perceptions – warns the reader against misinterpretations of the doctrine to which the history of thought shows the mind is prone. The Platonists are conspicuous for their discovery of essences, but they give them not only existence but prerogative existence. Essences are not models nor causes, nor intrinsically good. Every bad thing illustrates an essence as fully as things that are excellent. The idealist also misconceives essence; he is so overpowered by its discovery that he holds that it is the only existence, so that matter does not exist. The right conclusion, however, is that matter is the only thing that does *exist*, that works, that is causal and efficient. It is never known immediately, but only symbolically through the essences that it fortuitously causes to vegetate in the mind.

Mr. Santayana has nothing but scorn for those who doubt the existence and omnipotence of matter. The more sceptical we are of the existence of anything given, the greater the practical assurance of things which are not given to mind. Essences are only poetic, aesthetic, objects of immediate contemplation. But besides consciousness, which holds and enjoys these essences, perception and intuition, man is primarily a living body striving to make its way in a world of other bodies that have no interest in its success and failure. To have survived at all in an adventitious world means that the animal body has acquired some degree of adaptation to the material medium which determines its destiny. In the realm of essences the mind is purely contemplative and at play. But the body has to work to live; it has to meet and adjust itself to hard circumstance. The organized structure of the body in its achieved adaptation to physical surroundings or what are usually called instincts, reveals to us such attachments to the world of existence as essences may possess. These instinctive adaptations are common sense, or as Mr. Santayana calls them, animal faith. And as it is by poetry and the imagination that we live in the world of essence, so it is by animal faith that we ascertain that some

of these essences are symbolic of material things since they serve us in judging the material environment, in securing meat and drink, and averting for a time disease and death. Essences are present and timeless; but the perpetuation of the body depends upon memory, prudence, foresight, upon concern with what is not given, with what alters and is in time. It is this concern with time, this need for readiness to deal with things not given, not present in sensation or imagination, which selects those essences that are significant of something beyond themselves, which constitutes them transcendent, or cognitive of things beyond themselves. As with Spinoza, essence is mind, existence is matter.

Essences remain essences, the proper and rewarding objects of aesthetic contemplation and the free play of mind. But their adventitious conjunction with the needs of the animal body gives some of them practical intent and makes truth and error possible as they are used rightly or wrongly to signify some feared or hoped for object. Science changes the style of essences which are employed, because science has to meet larger, more public and remote needs and conditions. But it springs from the same wedding of essences to animal requirement and its objects differ from the essences of mythology only in that they are kept closer to the tests of existence applied to the determination of a living creature to go on living. "External objects interest man for what they do, not for what they are; and knowledge of them is significant, not for the essence it displays to intuition (beautiful as this may be) but for the events it expresses or foreshadows. It matters little if the very existence of external things is vouched for only by animal faith and presumption, so long as this faith posits existence where existence is, and this presumption expresses a prophetic preadaptation of animal existence to the forces of the environment." The practice of the arts is our most reasonable assurance of the existence of things beyond mind and perception.

It is impossible to render an adequate account of Mr. Santayana's new book. I have confined myself too closely and literally to such phases of it as may illustrate merely its title. If Mr. Santayana desired revenge upon those who have assumed that because he subordinated dialectic to expression, he lacked logic, he has it in this book. For continuity and subtlety of dialectic the book, though couched in a radically different philosophy, is worthy of Mr. F. H. Bradley, the master of living dialecticians. Indeed, it is so closely wrought and so sustained that it is to be feared that those who did not find coherent system in his earlier writings will not discover it here. Mr. Santayana promises a sequel; I shall make no adverse criticism of this book beyond saying that the sequel is badly needed. It is a delicate enterprise to discount practical intent and the busy life of man in behalf of aesthetic essences and their contemplation, and then to rely upon the practical needs, acts and sufferings of man to make sure of the existence of anything, and to render essences applicable to things and expressive of their careers. A priori one

would say that both things cannot be done, and that having surrendered so much to a naturalistic pragmatism Mr. Santayana must surrender more. But succeed or fail, the enterprise is technically one of the most exciting undertaken by any contemporary philosopher. And those who are not excited by the technique of a virtuoso will as always be rewarded in reading Mr. Santayana by the felicitous insight and the genial irony that find incidental expression on every page.

HALF-HEARTED NATURALISM

John Dewey. "Half-Hearted Naturalism." *Journal of Philosophy* 24.3 (3 February 1927): 57–64.

The ambiguity of philosophic terms and of the conceptions for which the words stand is indicated by the way in which Mr. Thilly cites, approvingly, Mr. Santayana's characterization of my mode of thinking as half-hearted naturalism.[1] To Mr. Santayana, naturalism is a desirable thing; the short-windedness of my devotion to it is matter for adverse criticism.[2] To Mr. Thilly, my half-heartedness is the saving clause; it intimates an idealistic strain which in spite of myself gives a redeeming touch to what would otherwise be, I suppose, sheer mechanistic materialism. There is no word in the history of thought which carries more varied meanings than "nature"; naturalism shares in its diverse significations.

I am not equipped with capacities which fit one for the office of a lexicographical autocrat, and I shall make no attempt to tell what naturalism must or should signify. But I may take advantage of the opportunity to say what empirical naturalism, or naturalistic empiricism, means to me. I can not hope to offer anything new, or anything which I have not said many times already. But perhaps by concentrating on this one point I may make the tenor of my thinking clearer, and incidentally throw some light on why it appears, from two opposed ends of the philosophic gamut, to be half-hearted.

"In nature," says Santayana, "there is no foreground or background, no here, no now, no moral cathedra, no centre so really central as to reduce all other things to mere margins and perspectives" (p. 678 [this volume, p. ???]). The statement is dogmatic; I do not say this in reproach; Mr. Santayana professes himself a dogmatic naturalist, and everyone, in my conception, must be dogmatic at some point in order to get anywhere with other matters. But even a dogmatist may be asked the grounds for his assertion, not, indeed, in the sense of what proof he has to offer, but in the sense of what is presup-

[1] Thilly, the *Philosophical Review*, Vol. XXXV, p. 532, in an article entitled "Contemporary American Philosophy." Santayana, *Journal of Philosophy*, Vol. XXII, p. 680, in an article entitled "Dewey's Naturalistic Metaphysics." All further quotations of Santayana are from this article.

[2] *Ibid.*: "I am myself a dogmatic naturalist," p. 687 [this volume, p. ???].

posed in the assertion, from what platform of beliefs it is propounded. I can not think that Santayana supposes that it is self-evident to others or to himself that nature is of the sort mentioned. The sweep and import of the statement is the more striking in that Santayana professes to operate without any metaphysics and is confident that a whole-hearted naturalism is inarticulate, a kneeling, before the unknowable and an adjuration of all that is human.[3] Since knowledge of nature is not the ground for Santayana's statements as to its character, their ground, I take it, is negative and antithetic; the traits denied are those which are characteristic of human life, of the scene as it figures in human activities. Since they are found where man is, they are not, it would seem, attributable to anything but man; nature, whatever else it is or is not, is just something which does not have these traits. In short, his presupposition is a break between nature and man; man in the sense of anything more than a physically extended body, man as institutions, culture, "experience." The former is real, substantial; the latter specious, deceptive, since it has centres and perspectives.

To me, then, Santayana's naturalism appears as broken-backed as mine to him seems short-winded. It is in virtue of what I call naturalism that such a gulf as Mr. Santayana puts between nature and man – social or conventional man, if you will – appears incredible, unnatural and, if I am rightly informed as to the history of culture, reminiscent of supernatural beliefs. To me human affairs, associative and personal, are projections, continuations, complications, of the nature which exists in the physical and pre-human world. There is no gulf, no two spheres of existence, no "bifurcation." For this reason, there are in nature both foregrounds and backgrounds, heres and theres, centres and perspectives, foci and margins. If there were not, the story and scene of man would involve a complete break with nature, the insertion of unaccountable and unnatural conditions and factors. To any one who takes seriously the notion of thoroughgoing continuity, the idea of existence in space and time without heres and nows, without perspectival arrangements, is not only incredible, but is a hang-over of an intellectual convention which developed and flourished in physics at a particular stage of history. It is not pragmatism nor any particular philosophical view which has rendered this conception questionable, but the progress of natural science. One who believes in continuity may argue that, since human experience exhibits such traits as Santayana denies to nature, the latter *must* contain their prototypes. The new physics finds them necessary to describe the physical world in its own terms.[4]

[3] "A naturalist instinctively, ... who, heartily despising the foreground, has fallen in love with the greatness of nature and has sunk speechless before the infinite" (p. 679 [this volume, p. ???).

[4] The use of the terms "events" and "affairs" in *Experience and Nature*, which Mr.

There are many occasional statements in Mr. Santayana's expositions which indicate that his agnosticism is not as complete in detail as it is in formal official statement. In discussing specific matters he often suggests that he shares the belief of the ordinary man that human experience, adequately safeguarded by a normal organism and a proper equipment of apparatus and technique, may afford dependable indications of the nature of things that underlie it; that we do not merely fall back on an "animal faith" that there is some adorable substance behind, but that we come to reasonable terms with its constituents and relations. If one generalizes this position, then the main features of human life (culture, experience, history – or whatever name may be preferred) are indicative of outstanding features of nature itself – of centres and perspectives, contingencies and fulfillments, crises and intervals, histories, uniformities, and particularizations. This is the extent and method of my "metaphysics": – the large and constant features of human sufferings, enjoyments, trials, failures and successes together with the institutions of art, science, technology, politics, and religion which mark them, communicate genuine features of the world within which man lives. The method differs no whit from that of any investigator who, by making certain observations and experiments, and by utilizing the existing body of ideas available for calculation and interpretation, concludes that he really succeeds in finding out something about some limited aspect of nature. If there is any novelty in *Experience and Nature*, it is not, I should say, this "metaphysics" which is that of the common man, but lies in the use made of the method to understand a group of special problems which have troubled philosophy.

Experience thus conceived is obviously opposed to the usage of the word in the English psychological tradition, a divergence which I was at some pains to point out in criticizing the latter. I consider myself justified, however, in departing widely from the strain of Locke and Hume and James Mill, because I believe that I am only reverting, with some critical purification, to the implications of its everyday untechnical meaning. Experience, thus conceived, constitutes, in Santayana's happy phrase, a foreground. But it is the foreground *of* nature. If I differ from Santayana as to this latter point, the difference lies in that he thinks of the foreground as a screen which conceals the background; to me it conducts our thought to the background. Apparently he conceives of the foreground as lying between human intuition and

Santayana finds redolent of a submergence of real "nature" in an all-absorbing human moralism, was dictated by the fact that physical science is now compelled, on its own behalf, to employ, if not these words, at least these ideas. On the philosophical side, it is dictated by the fact that the metaphysics, adhered to as far as I can make out by Santayana, which treats nature as a single substance whose parts and changes as such are illusory, is a flight of metaphysics which is beyond me, and which appears to be a survival of a rationalistic spiritualism which he officially repudiates.

experience and the background; to me human experiencing is the foreground, nature's own. He also may think that the background alone is nature to the exclusion of the foreground; I am not sure. But I am sure that the foreground is itself a portion of nature, an integral portion, and that nature is not just the dark abysmal unknown postulated by a religious faith in animality, especially since on such a view animality itself becomes a matter of faith.

Holding these views, the reader may dimly imagine the shock I felt when I read that it is axiomatic with me that "nothing but the immediate is real" (p. 683 [this volume, p. ???]).[5] A large portion of Mr. Santayana's article is a dialectic development of the consequences of such a belief, and naturally a destructive one. Since he thinks the view is mine I can only be grateful to him that he did not devote his skillful dialectic to showing that the whole of *Experience and Nature* is a mass of contradictions; the doctrines of "instrumentalism" with its assertion of recurrent identities in nature and of efficacious connections among natural existences, and of knowledge as always mediate and relational, evidently contradict the belief that only the immediate is real. But perhaps lack of interest in my discussion of specific topics on the part of Mr. Santayana saved me from that fate. I repeat, then, that I hold that everything which is experienced *has* immediacy, and that I also hold that every natural existence, in its own unique and brutal particularity of existence, also *has* immediacy, so that the immediacy which characterizes things experienced is not specious, being neither an unnatural irruption nor a supernatural imposition. To *have* traits, however, is not to *be* them, certainly not in any exclusive sense; and a considerable part of my discussion of special topics is an attempt to show that characteristic traits of the subjects dealt with are to be accounted for as "intersections" or "interpenetrations" (I could think of no better words) of the immediate and the nexional or mediatory, just as my criticism of various philosophical theories rests on showing that they have

[5] Lest silence be taken to imply assent, I state specifically that the positions taken by me are as distant as may be from those attributed to me by Santayana on pp. 685–686 [this volume, pp. ???]. If I held them I should admit his argument against them to be conclusive, but they are as unreal to me as they are to him. As he says, "practice precludes" any such beliefs, and while I am not as much of a pragmatist – or at least not the kind of pragmatist – as I am sometimes alleged to be, I am not so witless as to try to unite respect for practice with a belief in the exclusive absoluteness of immediacy. He says: "The dominance of the foreground, avowedly relative, has been turned from a biological accident into a metaphysical principle" (p. 686 [this volume, p. ???). But since I do not regard the foreground as an accident and since I also do not regard the mid-distant biological as an accident with regard to the physical, my "metaphysical principle" is that the related foreground may be taken as a method for determining the traits of the background. Treating the foreground as an "accident" illustrates what to me is unnatural in Santayana's notions. In lieu of many references which might be made to *Experience and Nature*, I content myself with one, p. 262.

isolated one phase at the expense of the other. That I do not think the immediacy which matters of experience have is specious or non-natural, I freely admit, for a nature that had no immediacy would not even exist, and the precious word "substance" would then turn out to be a synonym for that other word "essence." But perhaps such a naturalism as this is *too* whole-hearted to be acceptable.

Mr. Santayana says: "Suppose I say that 'everything ideal emanates from something natural.' Dewey agrees, understanding that everything remote emanates from something immediate. But what I meant was that everything immediate – sensation, for example – emanates from something biological" (p. 685 [this volume, p. ???], foot-note). This statement of what I believe is a specific case of the assumption that I hold that only the immediate is real and that the foreground is a foreground of nothing. So I repeat that while "consciousness" is foreground in a preeminent sense, experience is much more than consciousness and reaches down into the background as that reaches up into experience. I agree that the ideal "emanates" from the biological; I have been even criticized by other critics as if I held it to be a mere gaseous emanation from the biological. In reality I think that the ideal, sensation, for example, is as real as the biological from which it emanates, and, expressing a higher meed of the interaction of things than does the biological without sensation, is in so far I will not say more real, but a fuller reality. Nor do I believe that sensation is immediate, though it *has* immediacy. It bears within itself connections; it carries something of the remote conditions which call it into existence; otherwise it could never serve as a sign nor have cognitive value. And lest this disclaimer should be interpreted in the sense which Santayana points out in the context, namely, to mean that the *concept* of sensation is derived from biological concepts as terms in discourse, I add that I mean the derivation from the biological of the ideal in a literal existential sense. When Mr. Santayana goes on to say that it emanates from "the largely unknown or humanly unknowable process of animal life," there is indicated, perhaps, a difference. That the biological process and its history of eventuating (*pace* Santayana, for the suggestion of "history" and "event") in sensation is largely *unknown*, is only too evident. But to my mind this ignorance is not because experience interposes a veil, but because experience has not been sufficiently probed for its indications. To Mr. Santayana, if I understand him – and perhaps I do not any better than he does me – experience is such that "humanly unknowable" is his proper phrase. But in that case, why refer to the underlying conditions as biological? Or is it merely that all discourse, since experiential, is specious and conventional, and that one phrase is as good as another over against the abysm of unknowable Substance, God, Matter?

Santayana finds traces of my actual position, in as far as it is identical with his in the matter of the biological basis and substantiation of the ideal, in my

implicit behaviorism. But Mr. Santayana always makes it as difficult as possible for anyone to agree with him, and so he criticizes behaviorism as a peculiarly "American" form of externalism. The real gravamen appears to be that Santayana thinks that the behavioristic account of thought in connection with animal functions is bound to deny mind itself. There are psychologists who call themselves behavioristic who doubtless do precisely this thing. Santayana thinks that I must be either a behaviorist in this sense or a speculative egotist, and that my empiricism compels me, in spite of tendencies in the former direction, to become the latter. But the main thesis of *Experience and Nature* is that human experience is intelligent (including, of course, misintelligent) and emotional behavior. In other words, I have tried to bring together on a naturalistic basis the mind and matter that Santayana keeps worlds apart. The attempt, I know, is unusual; perhaps it is doomed to frustration, but I should not want that matter prejudged on the basis of my own ineptness. The trial is bound to be made again, and again, and I hope with increasing success. That success is impossible, given Santayana's premises, I am quite aware. But why not change the premises? My dependence upon the social or conventional medium may be too great, but my faith in it does not extend to believing that the last word on matter and mind has been said by it.

Mr. Santayana says that the foreground as conceived by me is a social world, a social medium. This he terms, somewhat invidiously, I think, convention. But, accepting the word "convention," I state what I have already implied, that "convention" is not conventional, or specious, but is the interaction of natural things when that interaction becomes communication. A "sign" may be conventional, as when a sound or a mark on a piece of paper – themselves physical existences – symbolizes other things; but *being* a sign, the sign-function, has its roots in natural existences; human association is the fruit of those roots. I can understand Santayana's idea that the social medium is conventional in a prejudicial sense only as another illustration of that structural dislocation of non-human and human existence which I have called a broken-backed naturalism. One of the basic contradictions which Santayana might readily have pointed out in my conclusions, if I really hold that only the immediate is real, concerns the social. He says that I have a "tendency to dissolve the individual into his social functions" (p. 675 [this volume, p. ???]), which, put in logical language, signifies that I resolve the immediate into the mediate. But since I find in human life, from its biological roots to its ideal flowers and fruits, things both individual and associational – each word being adjectival – I hold that nature has both an irreducible brute unique "itselfness" in everything which exists and also a connection of each thing (which is just what *it* is) with other things such that without them it "can neither be nor be conceived." And as far as I can follow the findings of physics, that conclusion is confirmed by the results of the examination of

physical existence itself. Since experience is both individualized and associational and since experience is continuous with nature as background, as a naturalist I find nature is also both. In citing Mr. Santayana's denial that nature has here, now, and perspective, I found myself in stating my own view compelled to use the plural form: – heres, nows, perspectives. I would not draw an inference from the mere use of a word, but Santayana's use of the singular form is suggestive that he thinks experience is something sole and private, and so thinking attributes a similar view to others who use the term. It *is* absurd to confer upon nature a single here, now, and perspective, and if that were the only alternative, I should agree with Mr. Santayana in his denial. But there are an indefinite multitude of heres, nows, and perspectives. As many as there are existences. To swallow them up in one all-embracing substance is, moreover, to make the latter unknowable; it is the logical premise of a complete agnosticism. But such an embrace also makes substance inconceivable, for it leaves nothing for it to absorb or substantiate. Moreover, the things which have heres and nows all interact with one another; they form a world of intercourse and association, though not of that communication which is a fuller exhibition of their connections with one another. If, perchance, I have exaggerated by my manner of speech the associated aspects of experience, it is because the traditional theory of experience dominated by a false psychology (as the traditional view of nature which Santayana reflects is dominated by a false physics) has ignored and denied that phase, assuming, as Mr. Santayana appears to do, a sole and lonely here and now.

It is not my purpose to criticize Mr. Santayana's philosophy, but to make an evidently much-needed statement of what I hold in distinction from what is imputed to me. This intention moves me even when I go on to say that I find two movements and two positions in Santayana which are juxtaposed, but which never touch. In his concrete treatments of any special topic when a matter of controversy to which traditional school labels are attached is in abeyance, he seems genuinely naturalistic; the things of experience are treated not as specious and conventional, but as genuine, even though one-sided and perverse, extensions of the nature of which physics and chemistry and biology are scientific statements. But he has a number of pigeonholes into which every philosophy must go with its appropriate, fixed, and absolute tag attached: – his own philosophy when it becomes self-conscious as well as those of others. When he lets himself go in any body of subject-matter, free from the influence of traditional and professorial labels, I not only learn much from him, but I flatter myself that I am for the most part in agreement with him. But when he deals with a system of thought and finds it necessary to differentiate his own system from it, his naturalism reduces itself to a vague gesture of adoring faith in some all-comprehensive unknowable in contrast with which all human life – barring this one gesture – is specious and illusory. Only in this way can I explain the fact that while I find myself in so much agreement with

him he is in such profound disagreement with me. The case seems to resemble that of the Irishman who said the two men looked very much alike, especially one of them. Barring that feature of Mr. Santayana's thought to which exception has been taken, I am happy to be that one.

Writings by C. I. Lewis

IDEA AND OBJECT

C. I. Lewis. "Idea and Object." *The Place of Intuition in Knowledge* (Ph.D. dissertation, Harvard University, 1910), chap. 6, pp. 121–144.

For every activity of thinking, for every purpose which is purpose to know, there must be something having the specific character of intuitions upon which this activity is directed. Otherwise the purpose is empty, and the activity has no content, no direction, and no meaning. Our activity of attending abstracts from the given, and thus what is discriminated becomes explicitly the presentation of the object of thought in the moment of attention. It is this presentation – which maintains, in the moment of attention, that specific character which it had in the awareness, – which becomes the *denotation* of the idea, – that which the idea identifies in the present experience as its object. But the presentation is not the entire denotation of the idea, for it does not fully satisfy the purpose of our thinking. Our purposive activity intends not only the discrimination of the presentation, but the understanding of it; and the presentation can be understood only as it belongs to that complex which we call the real object. The presentation of the object is not, thus, the completion of knowledge, but only the *sine qua non* of knowledge. Only as that which the idea denotes – the real object – is partially identified by its presentation in experience, does the idea *mean* anything. Once deprived of this specific intuitional presentation, the idea could never identify in experience anything which it intended. It would be forever shut out from the world of experience, and could never have any content but its own cogitatio. Strictly, it could not have so much as that, for our own thought process and our own purposing may become the content of idea only as it is *not* the activity which thinks but that which is thought. And if our purpose and thinking had not, when mediated, just that specific 'feeling' character which marks every other content, it could never be thought about at all, for no thinking could identify in experience that which such words as activity and purposing might *mean*.

Without intuition there can be no presentation of an object of thought, no object even partially identified, and *no idea*. Knowledge abhors a vacuum; pump out the specific content of the idea, and experience immediately refills the cavity, be it only with that feeling of emptiness which marks our failure to identify, as we intend, our object.

Yet certain objections may be raised against such a view. There are some kinds of ideas which, even if they have some experiential content in the wide

sense just suggested, are still not busy about anything which could really be called the presentation of their object. Abstract ideas seem to belong to this class, and there is some doubt about our thinking of the past and future. All that class of ideas for which there is no content which is 'mediated by our sense organs', offer difficulty. Also, the objections raised seem to find strong substantiation in all cases of symbolic thinking. The black marks on this page and the figures on the board are in no sense presentations of the objects of which they serve to remind us. They have not the specitic intuitional characteristics of these objects, and in no sense give us the qualitative richness of their content. The whole domain of 'imageless' thought contradicts our view.

These objections are based upon subtle errors. For the most part, they rest upon the narrow and technical interpretation of 'presentation' which is characteristic of empirical psychology, – the interpretation which contrasts 'images' with concomitant sensations and feelings and with 'reflexes'. As Myers notes, the presentation is stripped of all those characters which give it meaning.[1]

The contention with regard to abstract ideas alone seems to have a different force. There has frequently been, in philosophy, some tendency to regard abstract ideas as entirely different from *ideas as something abstracted*, and as having a content of entirely different nature. If it is difficult to find explicit statements which reveal this, still it is the general tendency which is marked by insistence upon the 'intellectual character' of logical processes and upon the sharp dividing line between class concepts and 'representations' of particular things.[2] It is the notion of abstract ideas against which Berkeley directed his opening argument of the "Principles." The tenor of Berkeley's remarks is instructive. In brief it amounts to this: We can have no idea of a horse which is neither black nor white nor piebald, of no triangle which is neither acute nor right nor scalene but is 'triangle in general'. We can, to be sure, reason about the character of triangles in general; because we can take a particular triangle and *neglect* all those features which are peculiar to it. In other words, we can refuse to *attend* to any character of the triangle except its having three sides and three angles. We can *abstract from everything but its triangularity.* Berkeley failed, it must be admitted, to recognize the implications of his own argument. But he has here set forth the true character of abstract ideas. They are ideas of something specific which may be abstracted from, discriminated in, many experiences, – of a single aspect or quality of many 'objects'. But if they were truly without any intuitional character, then an abstract idea – triangularity, for example – would fail to recognize any concrete triangle as its object; abstract 'redness' would no longer denote that 'indefinable' quality which we intend by it but would equally well apply to

[1] See p. 72, footnote.

[2] See quotation from Descartes, p. 4.

blue or green. We should have again the realm of ideas and the realm of experience, the class concepts and the classes, with an impassable gulf between. When abstract ideas are correctly understood, they are seen to differ only in one respect from others. *Every* idea comprehends no more than certain characters of its real object. It is an only partially specified 'what', and can never, in finite experience, be so specified as to comprehend completely the characteristics of anything concrete and individual. Some ideas, however, are specified to such a degree that, *owing to the selected character of our experience* – its difference from the all possible, – they denote only *one* object, and are thus distinguished from general ideas or class concepts. *As object of thought*, every individual real is comprehended only as an infima species – in a sense different from Aristotle's: its truly individual character – so far as this is not simply our ability to determine it uniquely, but is its own peculiar essence which would require infinite specification – is always transcendent of our thinking.

Memory ideas and ideas of imagination seem to call for little comment. Only as the memory idea is the presentation of something specific and intuitional can it be the memory of anything experienceable; and imagination would seem patently to be always a presentation of images. Imagination is 'constructive' only in the sense that it synthesizes 'reproductory' elements in a new complex. Its 'material' is intuitional. Indeed we may say that the memory and imagination differ most markedly from other kinds of awareness – vividness neglected – by the presence of an *additional* element.[3] Memory is marked by the quality of 'pastness', as recognition is characterized by the 'feeling of at-homeness'; and imagination differs principally in its relations to other possible content of thought, in a certain lack of coherence with the movement of awareness in general. Imagination, like the dream, may differ from 'real' experience only because sooner or later we give over our fancying or awaken.[4]

'Symbolic' thought is more difficult to deal with. There is no peculiar 'fourness' about '4' or 'given' about these marks which represent it. The plan

[3] Even the difference in vividness is often not marked. See Münsterberg: "Beiträge zur Experimentellen Psychologie," Heft IV, p. 18: "Wir sehen, wir hören, wir tasten einen Reizkomplex und fassen ihn so auf, dass wir die Lücken unserer Wahrnemung durch die Reproductionen früherer Erfahrung ausfüllen, ohne dass uns ein Unterschied zwischen objektiven Eindruck und subjektiven Zuthät überhaupt ins Bewusstsein tritt."

[4] Cf. Leibniz, "New Essays," ed. Macmillan 1896, p. 421: "The truth of sensible things consists only in the connection of phenomena, which must have its reason and is what distinguishes them from dreams; ... there is ordinarily some difference between feeling and imagination.... And the connection of the phenomena which guarantees the *truths of fact* in respect to sensible things outside us, is verified by means of the truths of reason; as the phenomena of optics are explained by geometry."

of a house has not the qualities of the house, nor is the sound of a word the presentation of its meaning. The fundamental error here lies in a dual character of our thinking, a sudden twist which we may often give it, and a consequent confusion of two aspects which *every* presentation may have, but which are especially noticeable in the case of 'symbols'. I suddenly reflect that my neighbor's clothes and physiognomy are not *him*, that what I see of the house is not the *house*, that 4 is not 'fourness', and so on. In each of these cases, I make an *abstraction* from the given which is guided and secured by a peculiar purpose of speculative character. I am reflecting upon the *transcendence* of the real object. I see '4', and suddenly *stop adding or subtracting* to note the insignificant and irrelevant character of this symbol itself; I *give over reading* to reflect upon these unmeaning marks. My thinking has a new purpose, a new *Aufgabe*, and I abstract from the given in an entirely different way.[5] But so long as I truly read or add or subtract, '4' is the presenttaion of a number or of the numerical attribute of something which I continually identify by that 'symbol' in experience. Only when I stop thinking of my object and *think of my thinking*, do these symbols cease to be presentations of real objects. The psychologist may tell me that I am a 'motile' and do much of my thinking in terms of sensations from the 'voluntary' muscles; or I may be of philosophical turn and think in 'vicious abstractions', which are psychologically the sounds of words in my own mouth. But the psychologist has his own peculiar purposes and ways of abstracting. Thus he has stripped my presentations of just those characters of meaning which, at the same time, he asserts that they have for me. Very likely, these 'motor settings' are the most important aspects of my objects, or their 'class names' may be the parts or characteristics which are most significant for my present purposes in dealing with them. As the unfortunate Romeo reflected, a name may be a very meaningful part of an object, and one very hard to abstract *from*. When the bookkeeper balances the cash, certain figures will cause a feeling of satisfaction, while certain others might bring him sleepless nights. They are *presentations* of *real objects* to him; they are certain characteristics of those

[5] See Titchener: "Experimental Psychology or Thought Processes." In this notion of '*Aufgabe*' Titchener presents from the psychological point of view much that I here attempt to treat epistemologically. "In my belief, two ideas (we should say two phases of a single movement of attention) do, under certain circumstances, make a meaning. What are the circumstances? I hold that, from the psychological or existential point of view, meaning – so far as it finds representation in consciousness at all – is always context. (We use 'meaning' differently.) An idea means another idea, is psychologically the meaning of that other idea, if it is that idea's context. And I understand by context simply the mental process which accrues to the original idea through the situation (normal '*Aufgabe*', – see footnote) in which the organism finds itself, – primitively, the natural situation; later, either the natural or the mental." (p. 175)

objects. It is on this account only, that he is a *thinking* being, while the adding machine which he uses is not. In certain ways our mental life may approach the character of the adding machine's operations. We may, especially if we are of a certain type of mind, 'mechanize' our 'thinking', and regard symbols only. But so far as we do this, our mental operations cease to have the *thoughtful* character and approach the unconscious reflex. In such a case also, the symbols – certain sounds or marks – cease to be symbols and become truly our *objects*. So far as symbols are really *symbols*, they are presentations *of* something, and are, for the purposes of our thinking, integral parts or aspects of those real objects. In any other *Aufgabe*, the idea which regards them denotes nothing but so many sounds or marks. They are comparable to words in an unknown tongue or messages in cipher.

For every idea, there must be a presentation which is, in part, that real object which the idea denotes. Any idea which did not contain this intuitional presentation, would have no object, no meaning, – would not be an idea of anything. Every real must be at least imaginable, if we use imagination in a loose way to denote the possibility of a presentation which is intuitional in character. The round-square is unreal because it requires us to present to ourselves roundness and squareness in a relation which they cannot have for our 'representative faculty'. The non-Euclidean geometries are false because they require us to imagine a straight line which is slightly curved – or not to represent their constructions to ourselves at all. No experience could present us with this kind of complex.[6] The *idea* of the unreal because unrepresentable is not empty, – it contains certain presented elements, but the *purpose* to synthesize these in a certain way must forever be invalid, because the elements do not admit of such relations. Hence the unreality of the object which a purpose thus to synthesize intends.

The idea must contain a presentation which is intuitional in character. Only in intuition do we find those qualitative or specious marks by virtue of which we can identify an object in experience. On the other hand, if the idea contained *nothing but* this presentation, then there could strictly be no such thing as knowledge. *Knowing* requires not only that something be presented, but that it be *understood*. And so far as the presentation is the total content of the idea, such an idea would be speechless, lost in the contemplation of an indefinable. Nothing could be predicated of such an 'object' of thought, because it would signify nothing beyond itself and no relation to anything else would be relevant to its nature. The idea must also contain those contextual relations through which the presentation may be defined, or at least denoted

[6] See the Appendix on "Intuition and the Non-Euclidean Geometries." If read at this point, this discussion may aid comprehension of the rest of this chapter by exemplifying the position taken and illustrating it in the application to a concrete problem.

with an accuracy sufficient for the purposes of present thinking. We search here for uniform relations. Certain relations of the presentation to its given context we find to possess a uniformity for all experiences which is germain to our understanding of the object. Certain others must be supplied by the activity of our thinking itself.

A perfect knowledge could come only with the clear and explicit presence to mind of all the context which would be required for the clear and detailed understanding of the presentation. But no finite mind can hold so much explicitly before itself at once. To return to the example of the books arranged on the shelf: We cannot clearly discriminate all the details, by which alone we know the arrangement to be perfect, at one time. Accordingly there results a *movement of attention*: we 'run over' the books in a certain fashion, assuring ourselves of the relations of each book to it immediate neighbors. In this process, each book, as we discriminate it, is still regarded in its relations to all that portion of the collection whose order we have already surveyed, though the first books and their relations again belong to the awareness content from which they were in turn discriminated. We might speak of this as a 'secondary awareness'. It's different significance for knowledge – difference from primary awareness – is at once evident. It is distinguished by the fact that it belongs to a *synthesis which is maintained with each succeeding discrimination.*

We must pause for a moment to investigate the nature of this movement of attention. It is necessitated by the limited character of our 'field of attention', is maintained by our purposive activity and differs from the movement of the awareness moment. The movement of awareness is just that flux of things, indifferent to our purposes, which characterizes experience. It is not so baffling and subversive of our interests in knowing as Heracleitus thought, – unless, indeed, one be dominated by that purpose to abstract these characteristics and ignore all others which characterizes some minds. Yet it is not that transition or movement which marks the progress of thought itself. If it were, we should not need to be conscious at all, – as has already been noted. The uniformity our purposes seek would forever be presented to us. On the other hand, the movement of attention, in the sense intended, – the progress of thought – is just that kind of transition which marks our 'running over' the books. It subserves a *single purpose to know*, which, though it has its phases, has still its unity. Either one of these movements – of awareness or attention – may dominate the other. The movement of awareness may control, and then we have the turning of attention which 'disrupts' the process of our thinking and presents us with 'new' objects. Or the movement of attention may control, and then we have a purposive activity such as 'going to find out', my opening the book, or moving the object or my position relative to it. This activity has its significance for knowledge, but is not strictly the activity of knowing itself.

We are now in position to approach the problem of the relation of idea and object. For *the unity of the object is the unity of our purpose to know.* Certain 'concretions in experience', certain relatively stable wholes which are concerned by our 'everyday' purposes, are the 'real objects' of our commonplace thought, but these complexes have no peculiar significance for epistemology. The book, the shelf of books, a single page, the library; – each of these may in turn be the real object of one's thought. But no one of these, as real object, may be exhaustively presented in a momentary experience. None of these may be identified simply with one's present explicit presentation of it. However small or simple any real object may be, still its reality always transcends any particular experience of it. We never know any object in such a way that there is nothing further to be found out about it. It is an imperative of our nature as thinking beings that we so regard every presentation and every synthesis of such. For only thus do we secure the unlimited possibility of valid activity of knowing. The possibilities of reality, for knowledge, must be inexhaustible. Further thinking, further explication of a single purpose to know, can never be absolutely purposeless. However much we may have been active in thinking about any real, we may still be further active with regard to it. Moreover, experience in general, seems to validate this imperative, though with regard to any *particular* real, it remains – from the nature of the case – necessarily a postulate. Further thinking of *this* object is never absolutely but only relatively purposeless. It is purposeless because some other real 'demands our attention'. The further knowing of *this* real, under the pressing character of experience, is morally blameworthy.

The real object always transcends its presentation. The complete understanding of this presentation requires the complete satisfaction of this particular purpose whose unity is the unity of the real object. Thus the knowledge of the real object is demanded by the presentation of it. And this knowledge requires a movement of attention.

So far, then, as attention *has performed* its selection from the awareness and its synthesis of successive discrimination, the real object lies in the secondary awareness. It is distinguished, at every instant, from other awareness content by its significant relations to or coherence with the presentation of the moment. So far as this discrimination and synthesis *is being performed*, the real object *is* the presentation of the moment. So far as this is still *to be performed*, the real object lies still in the simple awareness, or belongs to further possible experience.

These two – simple awareness and further possible experience – should not, in this connection, be confused. Suppose, for instance, I set about describing a certain building. I add detail to detail, constructing it in my thought. But somebody interrupts and says, "And it has a tower on the north-east corner." "To be sure," I reply, "I merely forgot to mention it." That detail I have omitted to bring into my construction, though I was all along dimly aware

of it. So far as I readily accept these emendations with the feeling that it was merely an omission of attention, it is probably true that they were in some sense present to my mind. But suppose that one add, "And there is an egg and dart moulding just below the cornice." I doubt it, or admit that I shouldn't have been able to give this detail. Here is a limitation of my knowledge of the real object which is of a different kind. I know Memorial Hall in the sense that I can distinguish it from the Germanic Museum and the Boston Public Library, but not in the sense that my idea of it may ever exhaust its wealth of detail. I can adequately identify it only because all the possible variations of architecture are not presented in my experience. I know a certain book, but doubtless certain alterations of its contents could be made without my detecting them. I always recognize that *some* further details of my idea await further experience of an appropriate kind. When my synthesis of what is relevant to my purpose in the *given awareness* is *complete*, still the real object transcends my idea and can be known further only by some movement of the awareness moment – my going to see the building or receiving further reports, and so forth.

In what way, then, do these transcendent characters of the real object belong to the object at all, since its unity is that of the *purpose to know*? Obviously, they belong to it because the purpose is never completely fulfilled by present knowledge. But this does not distinguish them from *different* details which may not belong to the object. And this brings us to recognize another character of the real object. For the real object must 'hang together in experience' in certain ways. Not only does its unity belong to the unity of our purpose to know, but the *unity of this purpose prescribes certain relations which must hold, in actual or possible experience*, among the various parts and aspects of the object. If a presentation is to be understood, it must be referred to some object that is real for some category. In order to be real in any category, this object must be such that the presentation will be related in certain categorical ways with that which may be presentation in a further possible experience. The kind of unity, kind of relations, prescribed by our purposes to understand presentations, differs for different categories. Most easily, we can point out that 'tangible objects' must have a certain spatial unity; all their parts must stand in certain space relations to one another – must be spatially continuous. We may also easily note that it is this difference of categorical relations which distinguishes true report from fancy, memory from actual or physical presence. Presentations of these different kinds of objects cohere with further possible experience in different ways. Each of these categories is marked by a kind of unity of the object which is required if the object is to be real in that category.

But while it is thus true that only possible experience can determine whether a presentation is of an object which is real in a certain category, yet every intuition is the presentation of an object which is real for *some* category. The

content of a false report does not have those relations to possible experience which would belong to it if it were *true*. But it is real as the *content of a false report*. I see before me on the paper a thin, curling, dark somewhat. I brush at it; it offers no resistance but remains. My eraser makes no impression on it. I move my eyes and it moves with them. Now I *understand* it: it is the after image of the electric light film. It did not have the *kind of relations* in my experience which would belong to a hair resting on the page, or to a pencil mark. But it has the kind of relations which go with it in experience of phenomena of the class to which I now refer it.

Whatever given is unreal, is unreal only *relative to the purpose to understand it in a certain way*, to so attend it, as to discover relations of a certain *kind*, which it would have, if real for that category, in possible experience. It is unreal for the purpose which seeks a certain kind of coherence in the object. Relative to some purpose to understand it in *some other* way, it must be real. Some other kind of relations to further aspects of a real object, it must have, for actual or possible experience. For the class of real objects to which it is properly referred, there must be a certain kind of coherence of various aspects or parts of the real object. The purpose to *understand* the presentation of any object, is the purpose to apprehend it in such categorical relations as it may have. *From the point of view of this purpose the presentation implies these relations of it. And these relations, again, imply those further characters, parts, and aspects of the object which are so related to the given presentation.* From the point of view of the present, these further characters, parts, or aspects are variables. The other side of the house may vary in many ways and yet be regarded as the other side of this real house. But they are limited variables. *Whatever else* the other side of the house may be, it must be *such that* it may have certain relations – spatial, for example – with that which is just now the explicit presentation of the house. It is limited by the necessity for these relations to the presentation. The presentation – as presentation of a real – must be understandable, which means that it implies other aspects or parts, standing in certain relations to it. *The real is, then, not simply the given, but the given plus that which the given implies in order that it be intelligible.* The real object must be intelligible. And the intelligibility of the real object means its transcendence of our presentation, our present experience, of it. It is thus that the present experience always implies something beyond itself. So far as the real object transcends my present experience of it, it is *whatever* stands in certain relations with this present experience.

This 'whatever', so far as it does not become that which is immediately next attended by my purpose to understand the given, is referred to an at least ideally possible experience. The qualification of 'ideal' cannot be omitted. Atoms and molecules, the other side of the moon, and the planets beyond Neptune cannot be presented in experience save in very fragmentary fashions. And if I recognize my limitations as an individual, the short span of my life,

and so forth, by far the greatest part of what is implied if my few experiences are to be intelligible is not possible experience for me. These limitations, however, while they are limitations of my finitude, are not the limitation of my finite *way of knowing. By possible experience, I must mean, then, that there can be, in the nature of the real objects, nothing which transcends my way of knowing and of identifying objects in experience.* Otherwise the postulate of the transcendent real does not in the least secure the intelligibility of my presentations, and thus – being no longer the postulate of the intelligibility of the given – is entirely gratuitous and unmeaning. The real objects as transcendent, is not such that it has another *kind* of reality from that intuitional one which I apprehend in the presentation of the object. *It is essentially something which would have that intuitional character – by which alone anything may be identified in experience – for any finite experience which could conceivably reach it.* If we can speak of knowledge of transcendent objects which could not appear in possible experience, such knowledge can have meaning only in reference to that which is not transcendent, only in reference to those presentations which imply its existence for their own intelligibility. The planets beyond Neptune are real only as implied by the perturbations of Neptune and other heavenly bodies: the other side of the moon is real only because the moon, as experienced, behaves like a solid body of a certain mass. The conception of any transcendent object can denote as its object, or identify in experience, only certain abstracted aspects of the objects of experience, or some representation which the mind creates in terms, finally, of intuition.

The real object, as object of ideally possible experience, means, further, that no experience may contradict this reality by finding *nothing* in those relations which imply it. No experience could come upon, here, either emptiness or an incomprehensible somewhat. We *know* the object, so far as transcendent, only as an 'X', a limited variable in certain relations. But we necessarily postulate, when we postulate the intelligibility of experience, that it *is not* a variable, but is a specific determination or value of that variable. We *know* no object, save as some aspect of it is presented to us in experience. And so far as this object, as real, is transcendent of our experience, still it must have this character of being schematically representable as that which stands in certain relations to what is given, and would have, for any experience which might reach it, the same intuitional or identifiable nature which characterizes present experience. This is the further specification of the statement that the real is the given plus that which renders the given intelligible; and this exhibits, in brief, the place of intuition in our knowledge of real objects.

But we are not yet ready to leave the problem. Though every part and aspect of the real object *is* identifiable only by some specious, qualitative characteristic, it is not at all certain that these 'indefinables' are essential to knowledge except in a functional way. It may be that the *particular* character

by which I identify anything may be entirely insignificant except in so far as it enables me to make the identification. Intuition may be germain to knowledge only because, as feeling beings, we must identify objects by their 'feels'. In what sense this last statement is correct, we have already discussed. We may further ask what the significance of these intuitional characters is for 'the world which we know in common'. If to be real means to be 'valid for all possible subjects', this problem may assume importance.

If the specific character of two colors were interchanged for the next child born, could it make any difference for his knowledge? Have we any assurance that, in general, the specific character which, for me, belongs to sounds may not, for you, belong to colors? Indeed, it seems impossible that the world should have the same specious characters for all of us. Your eyes are good; mine are astygmatic. My sense of smell is acute; yours is almost entirely lacking. You can distinguish three dimensions of feelings; I fail in every such attempt. You are short, and I am tall. If now we both see the object which is well across the table from us, not only is the sight impression different – we could not here allow that difference as significant; not only is the coordinated muscle sensation, or the feeling of reaching it, different – that also is unimportant – but the total presentation from which the psychologist abstracts these elements, our idea of that distance or space, as intuitional, cannot be the same. And this may be true though we act about it in the same categorical way. We may all be color blind to each other and never know it, merely because we distinguish approximately the same number of color variations. Our smell and taste and hearing are at least 'variously susceptible'.

The irritability with which such considerations as these are frequently met, I cannot help attributing partly to the fact that their lack of significance in epistemology is not usually accounted for. They are dismissed as trivial. Yet if they are trivial, that fact itself is significant of the role of intuition in any knowledge of the world that we hold in common. It points to the primary importance of a correspondence of our *ways of acting*, for only here can we discover surely the ground of common knowledge. If the colors, considered as specious intuitional qualities (which are indescribable save in some order) were not the same for you and for me, they would yet have the same significance for knowledge if our ways of acting towards them, schematizing them, were the same. But if what are distinct specious qualities for me remain identical for you, then our worlds will so far differ, because our ways of acting will differ.[7]

[7] Cf. Leibniz, "Discourse on Metaphysics", Prop. XIV, demonstration: "Nevertheless it is most true that the perceptions and expressions of all substances intercorrespond, so that each one following independently certain reasons or laws which he has noticed meets others which are doing the same, as when several have agreed to meet together in a certain place on a set day, they are able to carry out the plan if they wish. Now although all (the

And this may be the secret of the fundamental importance of that schema which is itself the order of our activities – temporal succession.

In order that we may have a world in common, certain basic relations of things – some basis of schamatization and determination in general must be the same for us, – the same not in specific intuitional character, but the same in the sense of *identification with the same category*. You must find a relation where I find, one, so far as we know the same reality; and your relation and mine must belong to the same category, to the same system of relations. For each of us the secret of this classification will necessarily be something intuitional; no other ground of identification is possible. But that is not to say that their specific character need be identical for both. Furthermore, if you are to find a relation where I find one, you must be able to discriminate what I discriminate. What are, for me, different qualities or aspects in experience cannot be identical for you. If they are, I shall *discover* your limitation, because your way of acting in the presence of this experience will be different from mine. The significance of the qualitative, intuitional character of experience and of objects for knowledge that may be called common lies only in its being the ground of analysis and synthesis, the ground of the categorizing of experience.

This, then, is the place of intuition in knowledge: It furnishes us with that material of thought without which our thinking activity would forever be empty. As the specific character of the presentations of objects, it is that by which alone any idea may, even partially, identify its object in the experience of the moment. As the given, it is in connection with the necessary postulate of intelligibility, the basis of our distinguishing the real from the all which is conceivably possible. Inasmuch as we seek to understand this given, it sets us the problem of determination or sufficiently adequate predication. Such determination, again, must depend finally upon intuition – upon such basal uniformities of relations as are given in experience. Not only does intuition give the only possible denotation which the idea may have in present experience, but so far as the object transcends our present experience, it still must have – as an object in its essential nature intelligible to our finite way of knowing – the character of intuition. The limits of intuition are the limits of intelligibility. Yet this significance of intuition for us still lies, at every step, in its connection with our purposive activity; only by regard for the intuitional characters of experience can we be guided in our logical ways of acting. Without our activity, intuition has no significance; without intuition, our activity has no ground or meaning.

individual perceptions) express the same phenomena, this does not bring it about that their expressions are exactly alike. It is sufficient if they are proportional as when several spectators see the same thing and are agreed about it, although each one sees or speaks according to the measure of his vision."

PROFESSOR SANTAYANA AND IDEALISM

C. I. Lewis. "Professor Santayana and Idealism." *University of California Chronicle* 14.8 (1912): 192–211.

Idealism is a general term applicable to a fairly wide range of philosophic doctrine. Berkeley holds that "to be is to be perceived." The position of Plato may perhaps be summarized in the statement that "to be is to be *con*ceived; the flux of sense perception is deceitful, and the real is transcendent of experience." For Kant, the object of knowledge must be both perceived and conceived: conception without perception is empty; percepts without concepts are blind. Fichte asserts that the real is the valuable; Hegel, that the real is rational and the rational is real. These campaign banners can hardly be got to march all in the same procession. It results from this divergence of doctrines that one may possibly refute Idealism with a capital "I" without hurting the feelings or damaging the arguments of anybody in particular. Whoever attacks Berkeley's position may be hailed as a comrade in arms by those who follow the Platonic tradition; while he who assails Plato's abstract ideas will do a real service to Neo-Kantians and Hegelians. But one who determines to annihilate Idealism in general is likely to waste his ammunition on a straw man, while his real opponents are outflanking him right and left.

This stalking Idealism in effigy has latterly become a favorite pastime. Certain philosophic writers in this country find it easier to play at refuting Idealism than seriously to attempt a construction of their own.

Professor Santayana, however, has not been one of this number. The spirit of his opposition is somewhat different – not directed so much against any particular thesis which he supposes all idealists to hold in common, but aimed rather at the general trend of idealistic thinking. You remember the Athenian who voted to banish Aristides because he was tired of hearing him called "the Just." Professor Santayana casts his vote against Idealism because he is wearied of its gentility. His poetic soul is sated with its eternal validities, and its protagonism of higher values. He finds its ethics "conventional and verbal," its morals "trivial and sanctimonious – based on authority instead of human nature, with salvation rather than happiness for their goal." It provides a cloak for superstition and allies itself with myth-making theologies. The separate charges in this arraignment cannot, we hope, be substantiated. Indeed they constitute an expression of sentiment rather than assertions to be proved or disproved. But this feeling that Idealism has become infected with

the germ of respectability, has even prospered too much and waxes effete and enervating, is probably not confined to Professor Santayana, though he has put it rather strongly. The fundamental insights of philosophy, like those of religion, ever require new and more vital forms of expression. There is, perhaps, this much of justice in Professor Santayana's attitude – that Idealism stands today just a little in need of fresh and vigorous restatement, shorn of all obsolete phraseology, and fully abreast of the best scientific and religious thinking of our time.

Such restatement is not, however, altogether wanting; and even if it were, that would constitute no excuse for denying the validity of the idealistic position. It is significant that Professor Santayana does not hold that the fundamental tenets of Idealism – unless it be Berkeley's – are false. On the contrary, transcendentalism is "true but trivial." I quote from the first volume of the *Life of Reason*: "It was a thing taken for granted in ancient and scholastic philosophy that a being dwelling, like man, in the immediate, whose moments are in flux, needed constructive reason to interpret his experience and paint in his unstable consciousness some symbolic picture of the world. To have reverted to this constructive process and studied its stages is an interesting achievement (he refers, of course, to Kant); but that construction is already made by common sense and science, and it was visionary insolence in the Germans to propose to make that construction otherwise. In the heat of scientific theorizing or dialectical argument, it is sometimes salutary to be reminded that we are men thinking; but, after all, it is no news."

This sounds persuasive; but if one conceive that there is anything really at stake, it is hardly convincing. It is not at once obvious why it is insolent to state explicitly what is already implied in science and common sense. One might suppose this to be the function of philosophy. If Kant's fundamental insight – which the passage quoted burlesques just a bit – is "no news," why treat Kantian doctrine as a view opposed to one's own? That one is bored by trivial truths is no excuse for serious disagreement. Moreover, it seems pertinent to ask how, if the primary principle of Idealism is true, the Naturalism which it controverts can be also true. The fact is that Idealism draws from this main premise certain consequences which Naturalism finds it convenient to omit. If we need constructive reason to interpret our experience, then at least experience needs interpretation, and the only interpretation possible is that which is made in the light of constructive reason. The conditions, further, which reason in its constructions imposes upon the object of thought must apply to all reality which is intelligible. And so on: – I hesitate to bore you further with the consequences of this "trivial truth," especially since they are already familiar.

Naturalism is not primarily a positive but a negative doctrine. It does not seek to expand our knowledge of realities so much as to correct certain

errors and to limit the field of significant truth and our method of attaining it. For Naturalism, the limits of knowledge are the (ideal!) limits of natural science, and the realm of knowable reality is bounded by causal and mathematical explanation. Anything further would be myth and superstition – or mere verbiage. The only laws of reality are those of mechanics and mathematics, with their derivatives. The laws of constructive reason, you observe, are forgotten in this enumeration. The naturalist may be a materialist and reduce the cosmos, life, mind, thoughts, purposes, and ideals to a concatenation of atoms and molecules, distributed according to the laws of motion. Or he may feel that the hypothesis of molecular matter smacks of metaphysics, and prefer to remain agnostic with respect to the substrate of reality. He seems then to be confined to the assertion that the world is full of a number of things; for further particulars consult the encyclopedias of natural science. His philosophy seems reduced to the aphoristic type, a series of wise observations about life.

Idealism, on the other hand, does not deny the validity or importance of scientific description. Instead, it insists upon it. Idealism does not even deny the reality of matter, the popular supposition to the contrary notwithstanding. Of course, if one mean by "matter" a something-I-know-not-what which is totally indescribable save as that in which qualities inhere, we must deny it. But science has no interest in such a supposititious substance, because it would explain nothing. The matter of science may be represented under a variety of forms, some of which are possibly true hypotheses while others are merely ideal constructions for convenience of treatment. The three dimensional continuum of mass points is of the latter type. The physicist no more supposes that force can be exerted upon a single mass point than he supposes that the weight of a lever can be concentrated at its center of gravity. The mass point is merely a convenient symbolism which simplifies the procedure of mechanics. The question whether mass points actually exist, or how space can be filled by indivisible and non-extended entities would, consequently, be meaningless. With atoms and molecules the case is different. There is no reason, except some advanced by scientists themselves, why a single molecule or atom may not be as real as an alum crystal or a drop of water. That no one can have any direct experience of a single molecule is no objection to their reality; the same may be said of the other side of the moon. To be sure, the scientist himself is likely to regard atoms and molecules either as merely ideal constructs, like mass points, or as at least hypothetical and doubtfully real. The reason is not, however, that no one has directly experienced them, but rather that not all the phenomena of which physics and chemistry treat are readily explainable on this hypothesis alone, and that, in any case, other possibilities are equally conceivable. But if we were once sure that no other hypothesis would explain all the facts, while this one would, both science and idealistic philosophy would confidently assert that atoms and molecules are

real. Reality must be through and through intelligible – that is a fundamental thesis of Idealism. If physical and chemical phenomena were inexplicable save on one hypothesis, then that hypothesis must be true. Idealism stands ready to insist upon the existence of matter, if by matter is meant anything which is *itself intelligible* and is required for the truth of science.

This digression with reference to the matter of science has been necessary in order to avoid misunderstanding. For I now have to say that Idealism would deny the existence and the possibility of that "matter" which figures in Professor Santayana's philosophy. The term "matter," he tells us, has two meanings. One, the scientific, you are familiar with. The other, which he calls the "literary or philosophic" meaning, is the sense in which he uses the term. When he styles himself a materialist, he intends no reference to atoms and molecules, mass points, or ions or electrons. The matter in question is a modification of Aristotle's ὑλς or stuff. It can neither be described nor adequately characterized, for reasons which will appear. But its function, as Professor Santayana represents it, is clear.

There is a difference between the idea or definition or essence of a thing (Aristotle's "form") and that thing's existence. This difference is one with respect to matter. Some essences are materialized; others are not. This is *not* the difference between thought and external reality, with which it might easily be confused. For a thought, too, is materialized when some one has it or thinks it. The distinction is, rather, that which holds between actuality and mere possibility – between the third dimension and the fourth, between you and your twin brother, between the thought which somebody thinks and one which somebody *might* think. The merely possible lacks *matter*; the actual has it or is constituted by means of it. The actual is, then, the conceivable or merely possible – the essence – plus matter.

The distinction thus indicated between essences and existences is, of course, a valid distinction. The question why some things exist, while others which are equally conceivable do not, is one which it is permitted anybody to raise – and answer if he can. But the problem is not solved, or even rendered intelligible, by saying "matter." "Matter" then becomes only another name for the problem.

The difficulty with this matter is that it can never be pried loose from the essences in union with which it exists. This is the more troublesome because the essences can readily be separated from matter. The merely possible – e.g., a piece of furniture you would like to have made – is still conceivable or definable. It has a definite nature. You know what you mean, though you do not find it in experience. This desk is the union of its essence with matter. We can separate out in thought its essence – as it was for the person who planned it – from its existence. But when the essence is abstracted from its existence, the matter of it seems utterly to disappear. Do I hear some one murmur "planks"? No, the planks from which the desk was made, or the kindling

wood into which it might be converted, are different from the desk. They are not the matter of the desk, but instead, the union of a different essence with matter. When we divide in thought the essence from the matter of the desk, we cannot conceive or describe the matter. It seems utterly to have lapsed. Essences by themselves are conceivable; matter by itself is not. Not only is this matter nowhere to be discovered out of combination with some essence, it cannot even be imagined. Unlike the matter of science it has no particular nature or properties, has no place in space or time, and is totally incomprehensible. Necessarily so, since to describe it or define it would be to give it an essence – a definition or idea – which *qua* matter it cannot have. Matter is the universal dough which lends itself to every shape, but has no shape itself. It is the great Nothing-in-particular.

It looks a little as if Professor Santayana intended us to think that he has solved the problem of existence by conceiving the inconceivable. As a fact, he has only given us a name which names nothing and has no meaning. His "matter" neither explains anything nor can be itself explained. He has indulged a little in that mythology which he attributes to Idealism, has called attention to a problem – probably an insoluble one – and then escaped into the realm of poetic fancies. We admit the problem, but we cannot seriously follow him. The possibility of such an incomprehensible substance as he offers us is automatically ruled out by that trivial truth of transcendentalism that we can and must interpret experience in the light of constructive reason: that it is meaningless to call anything real whose nature we can never understand.

This discussion of Matter as it appears in Professor Santayana's doctrine lies somewhat aside from our main theme. His materialism is *sui generis*, and its difficulties are not those of ordinary materialism, which intends to assert that all reality is made up of atoms and molecules, or energy – the matter of science. With reference to this doctrine, the attitude of Idealism is clear. The idealist may grant and even insist that matter is real, but he emphatically denies that the real is matter. There are other elements and phases of existence. We disagree with the materialist because he would restrict unduly and falsely the realm of the real and the true. It is the same objection which we would bring against Naturalism in general. Indeed, the materialist differs from other naturalists only in his understanding of science itself. For him, the elements in terms of which phenomena are explained by science are the fundamentally real things; for other naturalists it is the phenomena explained, rather than the elements into which they are analyzed, which are ultimately real.

So long as the naturalist is merely enunciating scientific truth, or even scientific hypotheses, Idealism has no quarrel with him. He is seeking to render some department of experience intelligible and to control nature in the interest of humanity. In this, the idealist, like every other sane person, should be his well-wisher and co-worker. It must be admitted that an idealist here

and there has sometimes failed in this respect to be true to his principles, and some have even sought to make capital out of the difficulties of science in its attempt to formulate self-consistent and sufficient hypotheses. Such an attitude is not only captious but subversive of the interests of philosophy in general and of Idealism in particular. We have nothing to gain by taunting the scientist with mistakes and difficulties within the field of science itself.

This statement must not, however, be taken as an admission that philosophy has not the right to call attention to the limitations of science. Natural science inevitably imposes certain restrictions upon itself. It confines its problems; consequently its solutions are equally circumscribed. Its business is to describe and to analyze; consequently its truths are such as can be discovered by analysis or set forth in descriptive generalizations. Science cannot take the place of philosophic thinking. The anatomical analysis of Nature into configurations of atoms, or the generalization of its metamorphoses in the laws of motion, is not the whole truth of Nature. Nor can the description of a brain process in physiological terms be the whole story of thinking or of the will act. There still remains the truth as to the validity of the idea, the rationality or irrationality of the will act – the truth of evaluation, of purposes and ideals. There still remains that truth which interests one who would take an appropriate attitude toward nature in general – its submission to or subversion of human interests, its kinship with our ideals or the opposite. If one choose to use a much misunderstood term, one may say that there is a truth of final causes, over and above – though never contradictory of – the truth of the efficient causes with which natural science deals. The scientist sometimes fears, I think, that final causes are intended as a substitute for further scientific investigation and description. This is natural; the word final suggests that the evidence is all in and the account closed. He suspects that because science leaves the development of the egg into the complete organism somewhat miraculous, we intend to explain it by saying that Nature is seeking to reproduce a certain form. If the term ever had such a meaning – and of this there is some doubt – at least it can have it no longer. The right of description belongs wholly to science. The facts which it is able to furnish us may leave much still uncomprehended. But that which is not yet causally understood can never be made intelligible by merely verbal explanation, or by the mere attribution of "purposes" to Nature.

Suppose, however, the entire process in question were adequately described and reduced to natural law. It is still miraculous, is it not, in the sense that it is wonderful. It is wonderful that the laws of development are what they are. It would be equally wonderful if they were otherwise and worked out different results. It is wonderful that Nature obeys laws at all – that it is uniform in such fashion as to enable science to describe and predict. That Nature seems to have in general that trend which we call upward, because we find that it more and more approximates to our ideals, is in this sense miraculous. If the world were

continually defeating human ends in greater number and more grievously, science could still go about its business of describing phenomena and discovering laws – unless, of course, the cosmos began to slough off its uniformities and become chaotic. It would then defeat the ends of science.

The whole truth about Nature is not told until it has been evaluated, measured by the standard of purposes and ideals. That it should have one value rather than another, that progress should be real instead of retroversion, that life is worth living or is not – these are significant truths not contained among the descriptive formulations of science. That there is no corner of the universe whose phenomena are not ultimately reducible to law, that the logical consequences of observed facts will themselves be observable facts, that the inductive method will continue to find itself validated by the processes of external reality – this conformity of the universe to the ideals of *science* is something which science itself can never demonstrate. It must take this conformity for granted before it can set up in business. These are the presuppositions which represent the faith of the scientist – his belief in the validity of his own thought processes and of his rational values.

That there is a truth of final causes means no more than this: reality can be completely understood only when it is viewed in the light of some end or goal – in other words, only in terms of values and ideals. This does not limit the nature of truth so as to exclude any even possible scientific account, because scientific thinking is itself one of the ways in which we seek to realize ideal ends and to control Nature in purposive ways. This is its only excuse for being. Science is engaged in converting the unintelligible into the intelligible and conquering our somewhat chaotic experience in the name of Reason. Science finds its beginning and end in ideals. Its truth is significant because it is valuable. The truth of values includes the truth of description; the truth of description does not include the truth of values. Hence Idealism includes Naturalism so far as Naturalism means the positive assertion of scientific truth, and parts company with Naturalism when that doctrine denies that there is any *other* truth.

But the naturalist here raises objection. He, too, deals with ideas and values; only his method, instead of being transcendental and verbal, is scientific. Thought processes are phenomena as much as chemical reactions; social institutions and ideals are as much the product of discoverable causes as are the phases of the moon. They have their laws, and are more or less predictable. Barring their somewhat greater complexity, there is no more difficulty in explaining mental and moral facts than there is in a problem of mechanics. Indeed, the mental and moral will probably some day be shown to be merely mechanical.

Here again it is necessary to guard against misunderstanding. Idealism does not deny that mental and moral phenomena can be causally explained. It is sometimes said that natural science cannot account for conscience, or for

morality, or for our artistic sense, or our civic ideals. With reference at least to morality, even Huxley, otherwise a consistent naturalist, has taken this position. But such a statement is misleading, on account of its ambiguity, and should be avoided. Science can perfectly well account for the *appearance* of our moral and social sentiments and for their *development* along with other phases of civilization.

The division of labor is a means to efficient dealing with environment. It enables the same energy to produce a larger result – more food, better clothing, deadlier weapons, and so on. The group which adopts it will, when brought into competition with a group which does not, or with isolated individuals, be bound to win. It will be wealthier, able to support larger families, will thus become the larger group and overcome the other by sheer force of numbers if in no more direct fashion. And the division of labor is only one among many practical advantages of social solidarity. Organized society means, however, just that abstention from certain kinds of competition – illegal and unsocial acts – which Huxley and some others take to be a controversion of natural processes. But the existence of the successfully integrated social group is possible only through the moral conduct of its members, and the natural processes which bring it about are quite analogous – though more complex – to those by which crystals are formed in a solution. Moral conduct is produced by natural processes in the same way as stronger bodies, better organized brains, and keener sensibilities.

One may object that the processes of Nature can indeed produce more appropriate reactions on the part of the organism, conduct which looks like and works like morality, but not necessarily moral feelings or a conscience. These are still unaccounted for. But the answer is obvious. A hen that liked the feeling of its head under water or had an insuperable aversion to pecking grain would never transmit these characteristics to any progeny, while fowls which felt better with a full crop would naturally flourish. Just so, if the advantages of organized society be granted, Nature will select those individuals and strains whose sentiments are compatible with group order and efficiency. Specific feelings are uniformly conjoined with certain stimuli and certain reactions, or perhaps with the coordination of the two. Whatever accounts for the organism's reactions also accounts for its feelings, in the sense that it discovers their uniform antecedents and accompaniments.

Science – anthropological and biological – offers the only possible explanation of the fact that those reactions which we call moral or artistic or logical are increasingly present in surviving human organisms. And the business of tracing the causal antecedents and physical accompaniments of moral sentiments and intentions, or of artistic perceptions, or logical decisions, belongs solely to the physiological psychologist. It may be true that, so far, psychology has had but indifferent success in its attempt to reduce the phenomena of will and judgment to law. But with those who would deny the possibility of

causal explanation in this field and make its facts entirely miraculous, Idealism has no more sympathy than has Naturalism. These objectors, if there be any such, are merely trying to turn back the wheels of progress and substitute mythology for science.

The attitude of modern Idealism on this point is unambiguous. It faces, with Kant, the problem of discovering what validity can attach to moral and religious values, consistently with the entire truth of science in the realm of phenomena. It cannot retract or qualify its assertion that all facts are to be understood. The time is long past when one may rationally suppose that the realm of phenomena contains odd corners to which science can never penetrate, or that the natural sequence of events is interrupted every now and again for the intrusion of a miracle. The divine can no longer be simply interpolated in the natural, the ideal artificially grafted upon the phenomenal. Or, if this is an error, and the natural is shot through and infected with the miraculous and scientifically incomprehensible, then the idealistic interpretation of reality is as much beside the mark as that of Naturalism. Both demand that the category of causality be applicable to whatever appears in space and time, applicable without exception. Neither would argue that the phenomena of religion or morality or art must be incomprehensible to science.

Since Naturalism can at once incorporate in its programme the results of natural science, the difficulty of Naturalism is not to account for the *appearance* of mental or social phenomena; it is to account for their *validity* that gives the scientist pause. That I should have the idea that I see an audience, or that the audience should feel uneasy in their present predicament, or that any other mental phenomena should occur in conjunction with particular brains, the psychologist may explain. Given sufficient data as to the nervous systems concerned and the stimuli impinging upon them, he should be able to predict these facts. But that the idea should be *true* or the feeling *justified* is an entirely different matter. Strictly, the scientist can offer no explanation of the validity of ideas or feelings simply because it is not his business. When he has shown how the thing comes about, has demonstrated that it occurs according to the laws of his particular science, he is done with it. Veridical perceptions and hallucinations, humane sentiments and moral perversions, poetic fancies and insane obsessions – all these he explains by the same laws and shows that they supervene with equal necessity upon their causal antecedents or physical accompaniments. That one mental operation is knowledge, another error, or that one motor impulse ends in right action, another in crime, does not in the least concern the psychologist, except as they reveal different conditions of nervous tissues or different stimuli. The truth or falsity of an idea, the rightness or wrongness of an intent, are, in the last analysis, judgments of value. That one is better and another worse, the descriptive scientist, merely as such, has no right to decide. As a *man*, he *must*; but that would signify nothing if it merely betrayed the workings of *his*

nervous system. Anyone may decide that his own brain mediates a judgment antagonistic to another's, but that does not discover any right or wrong, better or worse, except from the purely personal or subjective point of view. It discovers merely that one likes something or believes something. The objective validity of judgments and evaluations remains entirely problematic.

It is equally true of the sage, the insane person, and the pig that they have their beliefs and preferences. Who shall deny to the pig that raw potato is an end in itself and infinitely more valuable than wisdom? Why labor with the patient's delusions when one only pits one's own nervous system and its workings against another? This is a very old string I am harping on, but the argument is still as sound as when Plato directed it against the Naturalism of his day. Whoever would tell us that the *only* pertinent account of ideas and feelings is description in causal terms places himself at strange disadvantage. For one may reply: "I admit your contention, for the moment, and accept your argument and conclusion at the value which you yourself put upon them. Your brain – save the mark – is different from mine, or else subject to very different stimuli. I now understand why you hold such a strange philosophy. You inherited that kink in your gray matter – or it may be due to something you ate for dinner. Have you ever tried whiskey for it? That sometimes produces a new set of ideas and values." Or one may say, "The air waves from your vocal organs produce in my nervous system a disagreement with you. That is the whole truth of the matter." If validity is a matter of causation, all ideas and evaluations are equally valid, since all are equally caused.

The naturalist seeks to evade this issue. He points out that since man and Nature have evolved together, man finds himself – his nervous system, his beliefs and values – such as harmonize with the cosmos which has produced him. If it were otherwise, he would be quickly cut off, and his particular brand of truth would have no representatives. But while this is true on the whole, it admits of continual exception. No individual organism finds itself in perfect adjustment to environment. (We may remark in passing that the very idea of adjustment involves categories of value; every organism is equally a fact when and where it exists, and while it remains, all forces involved are equal and opposite. Again, values aside, why should evolution mean the survival of the *fittest*?) In any case, maladjustment persists along with adjustment; and the individual mind will, on that showing, always be a curious mingling of truth and error. This, you say, is no vital objection, since it is an obvious fact. Admittedly; but it points out nevertheless that objective validity is not secured to an idea because evolution has produced it. Moreover, each separate nervous system has equally been evolved by the processes of Nature, and accordingly, if the argument proves anything, it proves that all brains are equally good truth producers. Any attempt to escape this consequence will inevitably appeal, in the end, to some judgment of values. And the objective validity of these values will be presupposed. The naturalistic account must

appeal to that which Naturalism can never account for. The naturalist, if he explicitly states what his doctrine implies, becomes an idealist.

In this day and age, however, the naturalist further amends his position. Since all ideas are merely somebody's beliefs, and all evaluations somebody's preferences, he recognizes the impossibility of any absolute objective standard. He even prides himself a little upon this catholic point of view, and reviles the dogmatist in proportion. The truth is at best a name for the hypothesis that works. He sets up his ideas alongside Nature and contents himself with observing how Nature treats them. Perhaps he is even willing to set up *this* truth which he has just announced and observe what happens to it. We all have spells of wondering if Pragmatism will work.

But the naturalist, now turned pragmatist, is deceived by the vagueness of his own terminology. Even he is sometimes worried to know just what happens to an idea when it gets verified. It meets an experience which satisfies it, perhaps. But this phraseology is more blind than the first. The whole problem is to know how and in what sense experience can satisfy or refuse to satisfy an idea. The problem is real; the pragmatist does not solve it but only leads up to it and says, "Tag; you're it." The really important question is to know what is meant by an idea or a hypothesis "working." Attention will disclose that the pragmatist uses this word in a variety of meanings. A hypothesis in religion works when it makes you feel good. The idea of an all-seeing power that makes for righteousness works when it leaves you free to take moral holidays. So far it is true. A physical hypothesis works when you can deduce facts from it. Logic says that the hypothesis is thus rendered more or less *probable*, and reminds us that the truth may often be deduced from false premises. But Pragmatism asserts that if the hypothesis gives you the facts, it is so far true. Truth is only probability. Even the laws of probability are only probably true. Or more accurately, *probably* the laws of probability are only probable. It is probably best not to pursue this line of thought too far.

In general, an idea or hypothesis may be said to "work" when it is useful. This is the really important point. But usefulness is obviously a predication of value. The idea works if it is found to be valuable. However, it is just the objective criterion of value which the naturalist has failed to produce. By this excursion into Pragmatism he has only got himself into a vicious circle. In order to prove that our privately owned ideas and ideals have any value, it is necessary to secure their objective validity and truth. To the question "Has the idea which is simply the necessary result of a brain process any value?" the naturalist answers – as everyone must – "Yes, if it is true." But to the further question, "Is it true?" he now answers, "Yes, if it is valuable." If we simply assert the identity of truth with the valuable, we must remember that the account of the valuable from which the naturalist starts is that somebody likes it. And he has not got any further. Finding that he cannot bring subjective

feelings and ideas up to any standard of objective truth, he now calls upon us to bring the standard down to the feelings.

He has, it is true, another method of dealing with ideas and ideals. We are social beings, and find ourselves more or less in agreement. Our beliefs and sentiments are not merely subjective, because they are shared by others. Indeed, it is just the error of idealistic ethics that it is based on authority rather than that agreement which we find among men because of their community of feeling. Right and wrong, good and bad, must be decided by counting noses. Charity and head hunting are equally right in the communities which sanction them. The idea is not new: the Sophists invented it.

The real difficulty with Naturalism is not that it is too catholic and democratic, but that it is not enough so. If it would arrive at an objective truth and an objective standard of values, it must seek it in the very roots of human nature. Idealism appeals to authority, but it finds that authority is an agreement which leaves *no* nose uncounted – in the common rationality of mankind. Its initial premises are merely that the real is intelligible and that the truth is free from contradictions. In Ethics, its arch principle is only the law that there shall be law; that right conduct must be rational conduct, and that good wills can never find themselves really at cross purposes. One must so act that he can will the principle of his action as a universal law of conduct. One must seek his happiness by means which do not contradict the possibility of happiness for all. One must so think that the logical consequences of his idea do not contradict the idea itself.

These are no merely subjective standards, though they appeal to no external criteria which are not found in the subject of thought and action himself. They are ideals to be realized in the process of becoming what one means to be and attempts to become in every rational thought and action. Yet the realization of this goal is an infinite task – the vocation of humanity. The truth and objective value of these standards is revealed in the fact that to deny them or refuse them is to contradict one's self, and make life a meaningless muddle.

My task tonight is a rather limited one. If I should attempt further to reinstate Idealism, I should inevitably trespass in fields that belong to the further discussions for the year. Perhaps I have done so already. But I should like, in closing, to say just a little about the general method of Idealism. We are often accused of being dialectical and attempting to catch the adversary in purely verbal contradictions. But, after all, if we are to have any philosophy at all, it ought to be able to state itself without saying what it doesn't mean. Common sense is a good enough formulation of near truths to worry along with. To be sure, even this common stock is the accumulated wisdom of ages. It must have begun as a hard won truth which gradually seeped through the social medium. Common sense is inherited philosophy. Our present business must be to remove contradictions which remain, and state explicitly, if we can, that which is implied in common thought and action.

Because he has this faith in the common rationality of mankind, and believes that every thought and deed means to be intelligent, your idealist is the most presumptuous of men. He supposes that if you let any view develop its own implication and discover its own presuppositions, it will, in the end, assert that the real is rational – that the laws of constructive reason are the universal determinants and the framework of all that is knowable. It will find itself, after all, in agreement with the main thought of Idealism. Either that, or it will fall into contradictions which it cannot solve. Hence he favors letting every view have its say. Its truth will remain, while its errors will hang themselves in contradiction. Like Socrates of old, he is discouraged only when the opponent refuses to take himself seriously and avoids argument by calling names.

If it be natural science that is in question, he finds that the idealistic premises are inevitably presupposed. Science affirms the sovereignty of Intelligence over Nature, and is itself a process by which Reason takes possession of its realm. When science supplements itself with the statement of what it implies, and what it seriously means to do and be, it becomes Idealism.

Every doctrine must finally assume an absolute truth and an objective standard of values, simply because every view means to be *itself* absolutely true and universally worthwhile. These trivial truths are in themselves the only answer necessary to that Pragmatism which would reduce truth to probability. They constitute a sufficient refutation of that Naturalism which takes the significance of ideas and ideals to be exhausted by description and causal explanation.

REALISM AND SUBJECTIVISM

C. I. Lewis. "Realism and Subjectivism." *Journal of Philosophy, Psychology and Scientific Methods* 10.2 (16 January 1913): 43–49.

Idealists have so generally united in insisting upon a few important theses that their real and radical differences have been somewhat neglected. Perhaps there is something in the idealistic temper itself which leads to emphasis upon agreements. Since all views have their bit of meaning in the life of history, the idealist has been fonder of including than of controvert them. Hence, whoever holds to the non-existence of any alogical real, to the priority of epistemology, and the precedence of "truths of appreciation" over "truths of description," has been regarded as fundamentally right-minded and trusted to approximate the logical corollaries – one's own – of these principles. But whatever other result the present active criticism may have, it seems bound to break in upon the idealistic love feast. Nothing is more distressing than to be looked upon as discredited when it is one's neighbor, or the remains of one's ancestors, to whom this honor is due. One dislikes hearing of "idealism," when it is a subjectivist epistemology which is under discussion, – provided, of course, one's own view has no "taint of subjectivism."

That the attack of the six realists has been upon a subjectivist theory of knowledge, we have their assurance. That all idealists are thereby called upon to feel aggrieved may or may not be the case. Almost every idealism holds as important certain considerations about the predicament of the knower. But they need not be those which Professor Perry has exhibited in his paper on "The Egocentric Predicament,"[1] or the similar ones which figure in the introduction to "The New Realism."[2]

The idealist is there represented as arguing that all reals must be known, or that knowing is constitutive of reality, because no real can ever be discovered out of relation to a knower. The writer, for one, admits the invalidity of any such argument. It would prove – if it proved anything – altogether too much. For "known" here means "completely and explicitly possessed as content of consciousness," the identity of the object with present

[1] This Journal, Vol. VIII., pages 5 ff. See also "Present Philosophical Tendencies," pages 128 ff.

[2] Pages 11–12.

experience. At least it is this meaning which the realist seems to have in mind. The identification of reality with that which is present to some one's experience, or with the sum total of present experiences, carries sinister implications. For the whole problem of knowledge, as idealism sees it, turns upon the fact that the knowing experience means or intends something beyond itself, something which just now it *is not*. Otherwise, the experience might have any affective or esthetic value which it happened to possess, but it would not be knowledge. It is characteristic of knowing, as a human activity, that its meaning is not satisfied by the self-evident presence of its own experience or content of consciousness. Hence the part played in idealistic theory by "immediacy and mediation," and the recognition of the "inevitably fragmentary character of human knowing." Thus the history of idealistic epistemology in the last century might be summed up as the history of the recipe for *getting out of* the egocentric predicament. The recognition that nothing can be known except present content of consciousness would be fatal to the idealist's program, for it would dismiss his problem without a hope of solution. The subjectivist's dogma – that to be is to be perceived, or otherwise given in consciousness – is as distressing to idealism as to realism.

To be sure, the idealist often makes use of the conception of an ideal or limiting case of knowledge – the toilless knowledge of an absolute mind – for which knowing would mean just that detailed and explicit identity of thought and object which subjectivism maintains for knowing in general. But the idealistic theory of knowledge can get on very comfortably without hypothecating the *existence* of such a case of knowing, provided only its validity as an ideal be allowed.[3] As an event among other events, no such case of knowing can occur anywhere at any time. The epistemological interest in the absolute is the interest in the validity of an ideal. Idealism must explicitly deny that the total reality is identical with the experience of any finite knower. Hence it is, in general, more accurate to represent idealism as maintaining the essentially know*able* character of reality than to take it as holding that all reals are known.

The knower's predicament is, then, this: all that ever is and ever can be explicitly possessed by a mind which attempts to know will be a present experience; while the sure possession of this experience can never satisfy the interests of knowledge. To glorify the immediate data of consciousness with the adjective "independent" will not help the situation in the least. The present content is there; it is experienced; its "cash value" is already ours. If one has bitten an apple, one is certain of the taste in one's mouth. It matters

[3] Some idealists would disagree with this statement. But the following sentence would, I think, satisfy all but the out-and-out subjectivists.

not whether it be an independent taste or no. What knowledge requires is that a "credit" attach to the taste. It must be significant of the quality of the apple or of another taste; it must intend something which it is not. What knowledge signifies is its meaning; and meaning always reaches beyond the present experience. The problem of the validity of this meaning is the problem of knowledge, as idealism – since Kant – conceives it.

The idealistic interest in the egocentric predicament is to point this problem, and to call attention to the fact that unless it is solved by proving some necessary relation of reality to our ways of knowing, we have only the alternatives of skepticism or various unproved and improvable dogmas which can neither refute one another nor establish a constructive case.

We may state the problem in realistic terms. "Realism does not deny that when *a* enters into a relation, such as knowledge, of which it is independent, *a* now acquires that relation, and is accordingly different *by so much*; but denies only that this added relation is necessary to *a* as already constituted. Thus when *a is known*, it is a itself, as constituted without knowledge, which is independent of that circumstance. The new complex *known-a* is of course dependent on knowledge as one of its parts."[4] To restate the egocentric predicament: All the *a*'s and *x*'s which anybody can ever hope to know will be *known-a*'s and *known-x*'s, and as such dependent on knowledge, while it is the *a*'s and *x*'s as constituted without knowledge that are independent. The *known-a*'s and *known-x*'s will differ from these independently real *a*'s and *x*'s "by so much" – that is, by as much as they are affected by entering into relation to a knower.

All this is trivial enough until we remember that it is exactly the fundamental tenet of all skepticism, and the *bête noire* of every dogmatism. The critical question is: By *how* much does *known-a* differ from *a*?

To avoid misunderstanding, one possible objection based on this difference may be ruled out as negligible. *Known-a* differs from *a* as a relative from an absolute term, or as *a* unqualified from *a* modified by "known." *Known-a* is a complex or one end of a relation, while *a* may be simple and unrelated. This difference is something like that between "truth" and "unpleasant truth," or that between *x*-which-is-greater-than-*y* and *z*-which-is-less-than-*z*. The logical realism of Plato was troubled to make clear how the greater could be also less. Similarly, it might trouble the new realism to make clear how independent *a* can be identical with an *a* which is known, when *known-a* is *not* independent. The difficulty is to explain identity in difference when relations are external; to explain how *known-a* is still the same *a* and yet different by being related. But any objection which turned upon this difficulty which strict logical realism has with identities, would be likely to seem rather thin. Such logical puzzles suggest a *solvitur ambulando*. It is considerations

[4] Perry, Ralph B., "The New Realism," page 118.

of a quite different nature which have proved historically important for idealism.

It seems useless to deny that knowing is, in some sense or other, a kind of acting. That knowing is acting would seem to argue some effect in that upon which the activity is directed. Hence *known-a* seems likely to differ from real *a* by as much as the knower's activity affects it when it enters the knowledge relation. This will hold true whether the knower is an organism which functions in definite ways of its own, a nervous arc, or merely an unbiologized mind.

Knowing might be a transforming activity of a nervous receptor, so that real *a*'s might be apprehended as upside-down *a*'s or real substances known as complexes of colors and pitches and other "qualities," while the independent substances were not even imaginable. The divergence of real *a* and *known-a* might be as great as that between immaterial essences and space-filling bodies. The possibilities for persuasive dogmatism here are wide.

Or knowing might be, not a transforming, but only a selecting activity. In that event, *known-a* might differ from real *a* as a continuously flowing whole from a cinematograph picture of it, or as a valuable collection from a junk heap, or an ordered array from a chaos. Knowing might be selecting so as to satisfy certain practical interests. Our Euclidean space might be just such a prejudiced selection from an *n*-dimensional or undimensional reality. And so on, for the other characters of our world as we know it. If knowing is such an activity, dominated by interests, all the reality we can ever hope to know will be relative to those interests. If knowing is acting according to certain principles, then the world of our possible knowledge will reflect the legislation of those principles.

To revert to the predicament in which the knower finds himself; he seems to be confined to the experience of such realities as are, by their nature, capable of entering the knowledge relation – if knowing is passive, – or which are transformed or selected according to certain principles – if knowing is a way of acting. If knowledge transforms or interestedly selects, or if some reals are by nature unfitted to the knowledge relation, then known reality will so far fail to indicate the character of reality as it exists independently of knowledge. That independent reality is neither transformed nor otherwise misrepresented by *known-a*'s, the knower can not, from the nature of his predicament, ever know; while the seemingly active character of knowing lends color to the supposition that "knowledge" misrepresents the independently real.

The assertion even that there is such an independent reality must remain a sheer assumption. The realist may point out the fallacy of arguing from the fact that all *known* reals are known. And the subjectivist may retort that if there be any unknown real, it is an identical proposition that nobody knows it. That reality is not transformed when brought into the knowledge relation

is a similar assumption. The proof of it would require the impossible comparison of *known-a* with *unknown-a*. That an independent reality has this or that character must remain an unwarranted assertion, when all the *a*'s which can be known will be *known-a*'s.

When the number and variety of activist theories of knowledge is remembered, it seems a hardy dogmatism which opposes to them all the necessarily unproved thesis that the real is independent of knowledge; and then adds that this independent reality is already so finely divided that no analysis can ever be carried so far as to violate its nature; but that all the relations and all the organization which mind can "legitimately" think are also already there; in particular, that these independent reals maintain all the logical relations; and, finally, that any of these reals or any complex of them may enter into the knowledge relation – a notable case of a relation not already there – without being transformed. Such a happy conjunction of miracles reminds one of Leibniz's preestablished harmony. But this latter-day best-of-all-possible-worlds appeals to no sufficient reason.

Whoever takes the principles of knowledge to be legislative for whatever can properly be called real, and holds reality to be so far dependent on knowledge, will be assured – if he makes out his case – that *known-a*'s and real *a*'s are not of essentially different character, and that knowledge is objectively valid. But the person who recognizes his egocentric predicament and at the same time insists that reality is independent of knowledge and its conditions, is confined within the circle of his experience, whose relation to reality beyond he can not know. Hence, from the idealistic point of view a subjectivist is not one who takes reality to be essentially relative to knowledge, but one who takes it to be independent. Subjectivism and dogmatism are twins.

If reality is independent, while the knower can not jump out of the circle of his own experience, then we have the alternatives of skepticism – for the critically minded – or any one of a presumably infinite number of dogmatisms. None of these will be able to *prove* that reality is independent of knowledge, because such a proof would require the discovery of not-known reals and their comparison with those known. And none of these dogmatisms will be able to prove that independent reality has the character attributed to it, because the only reals which are, beyond doubt, independent, can not be investigated. Thus whatever is constructive in such a theory, will necessarily remain indemonstrable. The utmost that can be proved is that some other theorist's argument, – *e.g.*, the subjectivist's argument from the egocentric predicament, – does not prove his case. The subjectivist's *view*, as a dogma, can not be proven false; it can only be proven not proved. And every dogmatism can perform this service for every other.

If the foregoing is correct, it is no accident that the realistic doctrine is largely negative. Rather, it is inevitably the case that every such view should contain two parts; the more important consisting of proofs that the proofs – not the

views – of other theories are unsound; the other portion made up of unproven assertions about an independent reality. It is a psychological defect that flesh is heir to, that we are sometimes led to believe a doctrine because arguments for an opposing theory are invalid. The realist surely means to take no advantage of us in this respect. If realists have disproved certain arguments for the dependence of reality upon knowledge, they have not thereby established the independence of reality. If the realist be right, and idealism essentially subjectivist, it must, to be sure, renounce its claim to a critical foundation. But it would still remain a consistent dogma, and as good as any other.

If it is taken to be the case that realism has undermined the idealist's *proofs* that the logical relations hold among reals because reality is relative to a legislative reason, still the idealistic contention is as probable as any. The realist can not disprove the assertion. He can never catch a reality out of relation to human reason, in order to discover if it still maintains its conformity to logical principles. That the logical relations are found among things does not make realism any more probable. For if to be real means to conform to certain categorical modes of thinking, then it will be an identical proposition which asserts that these principles state the relations of real things. The realist can only set up his own counter assertion and return to the business of demolishing the opponent's proofs. Thus we might conceivably be presented with dogmatic idealism and dogmatic realism as equally consistent and equally unproved doctrines; and the choice between them might, then, turn upon pragmatic considerations of workability or temperamental preferences.

If the realist can advance no direct proof that reality not only may be, but *is* independent of knowledge, that the independently real not only might not be, but *is not* altered when it enters the knowledge relation, that reality not only may be, but *is* so finely divided that analysis can never misrepresent it, – and so on for his other contentions, – then his arguments must necessarily be confined to the refutation of the proofs of other theories. In that event his case can prosper only if he turns philosophy into a Donnybrook Fair and hits every non-realistic head that shows. Even so, he will not prove his case, but only establish its possible truth, – the impossibility of proving the opposite. If this is the utmost that can be hoped from a philosophic theory, it is well that we should recognize it, and pay our respects to Hume.

A PRAGMATIC CONCEPTION OF THE *A PRIORI*

C. I. Lewis. "A Pragmatic Conception of the *A Priori*." *Journal of Philosophy* 20.7 (29 March 1923): 169–177.

The conception of the a *priori* points two problems which are perennial in philosophy; the part played in knowledge by the mind itself, and the possibility of "necessary truth" or of knowledge "independent of experience." But traditional conceptions of the *a priori* have proved untenable. That the mind approaches the flux of immediacy with some godlike foreknowledge of principles which are legislative for experience, that there is any natural light or any innate ideas, it is no longer possible to believe.

Nor shall we find the clue to the *a priori* in any compulsion of the mind to incontrovertible truth or any peculiar kind of demonstration which establishes first principles. All truth lies upon the rational mind the same compulsion to belief; as Mr. Bosanquet has pointed out, this character belongs to all propositions or judgments once their truth is established.

The difficulties of the conception are due, I believe, to two mistakes: whatever is *a priori* is necessary, but we have misconstrued the relation of necessary truth to mind. And the *a priori* is independent of experience, but in so taking it, we have misunderstood its relation to empirical fact. What is *a priori* is necessary truth not because it compels the mind's acceptance, but precisely because it does not. It is given experience, brute fact, the *a posteriori* element in knowledge which the mind must accept willy-nilly. The *a priori* represents an attitude in some sense freely taken, a stipulation of the mind itself, and a stipulation which might be made in some other way if it suited our bent or need. Such truth is necessary as opposed to contingent, not as opposed to voluntary. And the *a priori* is independent of experience not because it prescribes a form which the data of sense must fit, or anticipates some preëstablished harmony of experience with the mind, but precisely because it prescribes nothing to experience. That is *a priori* which is true, *no matter what*. What it anticipates is not the given, but our attitude toward it: it concerns the uncompelled initiative of mind or, as Josiah Royce would say, our categorical ways of acting.

The traditional example of the *a priori par excellence* is the laws of logic. These can not be derived from experience since they must first be taken for

granted in order to prove them. They make explicit our general modes of classification. And they impose upon experience no real limitation. Sometimes we are asked to tremble before the spectre of the "alogical," in order that we may thereafter rejoice that we are saved from this by the dependence of reality upon mind. But the "alogical" is pure bogey, a word without a meaning. What kind of experience could defy the principle that everything must either be or not be, that nothing can both be and not be, or that if x is y and y is z, then x is z? If anything imaginable or unimaginable could violate such laws, then the ever-present fact of change would do it every day. The laws of logic are purely formal; they forbid nothing but what concerns the use of terms and the corresponding modes of classification and analysis. The law of contradiction tells us that nothing can be both white and not-white, but it does not and can not tell us whether black is not-white, or soft or square is not-white. To discover *what contradicts what* we must always consult the character of experience. Similarly the law of the excluded middle formulates our decision that whatever is not designated by a certain term shall be designated by its negative. It declares our purpose to make, for every term, a complete dichotomy of experience, instead – as we might choose – of classifying on the basis of a tripartite division into opposites (as black and white) and the middle ground between the two. Our rejection of such tripartite division represents only our penchant for simplicity.

Further laws of logic are of similar significance. They are principles of procedure, the parliamentary rules of intelligent thought and speech. Such laws are independent of experience because they impose no limitations whatever upon it. They are legislative because they are addressed to ourselves – because definition, classification, and inference represent no operations of the objective world, but only our own categorical attitudes of mind.

And further, the ultimate criteria of the laws of logic are pragmatic. Those who suppose that there is, for example, *a* logic which everyone would agree to if he understood it and understood himself, are more optimistic than those versed in the history of logical discussion have a right to be. The fact is that there are several logics, markedly different, each self-consistent in its own terms and such that whoever, using it, avoids false premises, will never reach a false conclusion. Mr. Russell, for example, bases *his* logic on an implication relation such that if twenty sentences be cut from a newspaper and put in a hat, and then two of these be drawn at random, one of them will certainly imply the other, and it is an even bet that the implication will be mutual. Yet upon a foundation so remote from ordinary modes of inference the whole structure of *Principia Mathematica* is built. This logic – and there are others even more strange – is utterly consistent and the results of it entirely valid. Over and above all questions of consistency, there are issues of logic which can not be determined – nay, can not even be argued – except on pragmatic grounds of conformity to human bent and intellectual convenience. That we

have been blind to this fact, itself reflects traditional errors in the conception of the *a priori*.

We may note in passing one less important illustration of the *a priori* – the proposition "true by definition." Definitions and their immediate consequences, analytic propositions generally, are necessarily true, true under all possible circumstances. Definition is legislative because it is in some sense arbitrary. Not only is the meaning assigned to words more or less a matter of choice – that consideration is relatively trivial – but the manner in which the precise classifications which definition embodies shall be effected, is something not dictated by experience. If experience were other than it is, the definition and its corresponding classification might be inconvenient, fantastic, or useless, but it could not be false. Mind makes classifications and determines meanings; in so doing it creates the *a priori* truth of analytic judgments. But that the manner of this creation responds to pragmatic considerations, is so obvious that it hardly needs pointing out.

If the illustrations so far given seem trivial or verbal, that impression may be corrected by turning to the place which the *a priori* has in mathematics and in natural science. Arithmetic, for example, depends *en toto* upon the operation of counting or correlating, a procedure which can be carried out at will in any world containing identifiable things – even identifiable ideas – regardless of the further characters of experience. Mill challenged this *a priori* character of arithmetic. He asked us to suppose a demon sufficiently powerful and maleficent so that every time two things were brought together with two other things, this demon should always introduce a fifth. The implication which he supposed to follow is that under such circumstances 2 + 2 = 5 would be a universal law of arithmetic. But Mill was quite mistaken. In such a world we should be obliged to become a little clearer than is usual about the distinction between arithmetic and physics, that is all. If two black marbles were put in the same urn with two white ones, the demon could take his choice of colors, but it would be evident that there were more black marbles or more white ones than were put in. The same would be true of all objects in any wise identifiable. We should simply find ourselves in the presence of an extraordinary physical law, which we should recognize as universal in our world, that whenever two things were brought into proximity with two others, an additional and similar thing was always created by the process. Mill's world would be physically most extraordinary. The world's work would be enormously facilitated if hats or locomotives or tons of coal could be thus multiplied by anyone possessed originally of two pairs. But the laws of mathematics would remain unaltered. It is because this is true that arithmetic is *a priori*. Its laws prevent *nothing*; they are compatible with anything which happens or could conceivably happen in nature. They would be true in any possible world. Mathematical addition is not a physical transformation. Physical changes which result in an increase or decrease of the

countable things involved are matters of everyday occurrence. Such physical processes present us with phenomena in which the purely mathematical has to be separated out by abstraction. Those laws and those laws only have necessary truth which we are prepared to maintain, no matter what. It is because we shall always separate out that part of the phenomenon not in conformity with arithmetic and designates it by some other category – physical change, chemical reaction, optical illusion – that arithmetic is *a priori*.

The *a priori* element in science and in natural law is greater than might be supposed. In the first place, all science is based upon definitive concepts. The formulation of these concepts is, indeed, a matter determined by the commerce between our intellectual or our pragmatic interests and the nature of experience. Definition is classification. The scientific search is for such classification as will make it possible to correlate appearance and behavior, to discover law, to penetrate to the "essential nature" of things in order that behavior may become predictable. In other words, if definition is unsuccessful, as early scientific definitions mostly have been, it is because the classification thus set up corresponds with no natural cleavage and does not correlate with any important uniformity of behavior. A name itself must represent *some* uniformity in experience or it names nothing. What does not repeat itself or recur in intelligible fashion is not a thing. Where the definitive uniformity is a clue to other uniformities, we have successful scientific definition. Other definitions can not be said to be false; they are merely useless. In scientific classification the search is, thus, for *things worth naming*. But the naming, classifying, defining activity is essentially prior to investigation. We can not interrogate experience in general. Until our meaning is definite and our classification correspondingly exact, experience can not conceivably answer our questions.

In the second place, the fundamental laws of any science – or those treated as fundamental – are *a priori* because they formulate just such definitive concepts or categorical tests by which alone investigation becomes possible. If the lightning strikes the railroad track at two places, *A* and *B*, how shall we tell whether these events are simultaneous? "We ... require a definition of simultaneity such that this definition supplies us with the method by means of which ... we can decide whether or not both the lightning strokes occurred simultaneously. As long as this requirement is not satisfied, I allow myself to be deceived as a physicist (and of course the same applies if I am not a physicist), when I imagine that I am able to attach a meaning to the statement of simultaneity....

"After thinking the matter over for some time you then offer the following suggestion with which to test simultaneity. By measuring along the rails, the connecting line *AB* should be measured up and an observer placed at the midpoint *M* of the distance *AB*. This observer should be supplied with an

arrangement (*e.g.*, two mirrors inclined at 90°) which allows him visually to observe both places *A* and *B* at the same time. If the observer perceives the two flashes at the same time, then they are simultaneous.

"I am very pleased with this suggestion, but for all that I can not regard the matter as quite settled, because I feel constrained to raise the following objection: 'Your definition would certainly be right, if I only knew that the light by means of which the observer at *M* perceives the lightning flashes travels along the length *A–M* with the same velocity as along the length *B–M*. But an examination of this supposition would only be possible if we already had at our disposal the means of measuring time. It would thus appear as though we were moving here in a logical circle.'

"After further consideration you cast a somewhat disdainful glance at me – and rightly so – and you declare: 'I maintain my previous definition nevertheless, because in reality it assumes absolutely nothing about light. There is only *one* demand to be made of the definition of simultaneity, namely, that in every real case it must supply us with an empirical decision as to whether or not the conception which has to be defined is fulfilled. That light requires the same time to traverse the path *A–M* as for the path *B–M* is in reality *neither a supposition nor a hypothesis* about the physical nature of light, but a *stipulation* which I can make of my own freewill in order to arrive at a definition of simultaneity.' ... We are thus led also to a definition of 'time' in physics."[1]

As this example from the theory of relatively well illustrates, we can not even ask the questions which discovered law would answer until we have first by *a priori* stipulation formulated definitive criteria. Such concepts are not verbal definitions, or classifications merely; they are themselves laws which prescribe a certain uniformity of behavior to whatever is thus named. Such definitive laws are *a priori*; only so can we enter upon the investigation by which further laws are sought. Yet it should also be pointed out that such *a priori* laws are subject to abandonment if the structure which is built upon them does not succeed in simplifying our interpretation of phenomena. If, in the illustration given, the relation "simultaneous with," as defined, should not prove transitive – if event *A* should prove simultaneous with *B*, and *B* with *C*, but not *A* with C – this definition would certainly be rejected.

And thirdly, there is that *a priori* element in science – as in other human affairs – which constitute the criteria of the real as opposed to the unreal in experience. An object itself is uniformity. Failure to behave in certain categorical ways marks it as unreal. Uniformities of the type called "natural law" are the clues to reality and unreality. A mouse which disappears where no hole is, is no real mouse; a landscape which recedes as we approach is but illusion. As the queen remarked in the episode of the wishing-carpet; "If this

[1] Einstein, *Relativity*, pp. 26–28: italics are the author's.

were real, then it would be a miracle. But miracles do not happen. Therefore I shall wake presently." That the uniformities of natural law are the only reliable criteria of the real is inescapable. But such a criterion is *ipso facto a priori*. No conceivable experience could dictate the alteration of a law so long as failure to obey that law marked the content of experience as unreal.

This is one of the puzzles of empiricism. We deal with experience: what any reality may be which underlies experience, we have to learn. What we desire to discover is natural law, the formulation of those uniformities which obtain amongst the real. But experience as it comes to us contains not only the real but all the content of illusion, dream, hallucination, and mistake. The *given* contains both real and unreal, confusingly intermingled. If we ask for uniformities of this unsorted experience, we shall not find them. Laws which characterize all experience, of real and unreal both, are non-existent and would in any case be worthless. What we seek are the uniformities of the *real*; but *until we have such laws, we can not sift experience and segregate the real.*

The obvious solution is that the enrichment of experience, the separation of the real from the illusory or meaningless, and the formulation of natural law, all grow up together. If the criteria of the real are *a priori*, that is not to say that no conceivable character of experience would lead to alteration of them. For example, spirits can not be photographed. But if photographs of spiritistic phenomena, taken under properly guarded conditions, should become sufficiently frequent, this *a priori* dictum would be called in question. What we should do would be to redefine our terms. Whether "spook" was spirit or matter, whether the definition of "spirit" or of "matter" should be changed; all this would constitute one interrelated problem. We should reopen together the question of definition or classification, of criteria for this sort of real, and of natural law. And the solution of one of these would mean the solution of all. Nothing could *force* a redefinition of spirit or of matter. A sufficiently fundamental relation to human bent, to human interests, would guarantee continuance unaltered even in the face of unintelligible and baffling experiences. In such problems, the mind finds itself uncompelled save by its own purposes and needs. I *may* categorize experience as I will; but *what* categorical distinctions will best serve my interests and objectify my own intelligence? What the mixed and troubled experience shall be – that is beyond me. But what I shall do with it – that is my own question, when the character of experience is sufficiently before me. I am coerced only by my own need to understand.

It would indeed be inappropriate to characterize as *a priori* a law which we are wholly prepared to alter in the light of further experience, even though in an isolated case we should discard as illusory any experience which failed to conform. But the crux of the situation lies in this; beyond such principles as those of logic, which we seem fully prepared to maintain no matter what, there must be further and more particular criteria of the real prior to any inves-

tigation of nature whatever. We can not even interrogate experience without a network of categories and definitive concepts. And we must further be prepared to say what experimental findings will answer what questions, and how. Without tests which represent anterior principle, there is no question which experience could answer at all. Thus the most fundamental laws in any category – or those which we regard as most fundamental – are *a priori*, even though continued failure to render experience intelligible in such terms might result eventually in the abandonment of that category altogether. Matters so comparatively small as the behavior of Mercury and of starlight passing the sun's limb may, if there be persistent failure to bring them within the field of previously accepted modes of explanation, result in the abandonment of the independent categories of space and time. But without the definitions, fundamental principles, and tests, of the type which constitute such categories, no experience whatever could prove or disprove anything. And to that mind which should find independent space and time absolutely necessary conceptions, no possible experiment could prove the principles of relativity. "There must be some error in the experimental findings, or some law not yet discovered," represents an attitude which can never be rendered impossible. And the only sense in which it could be proved unreasonable would be the pragmatic one of comparison with another method of categorical analysis which more successfully reduced all such experience to order and law.

At the bottom of all science and all knowledge are categories and definitive concepts which represent fundamental habits of thought and deep-lying attitudes which the human mind has taken in the light of its total experience. But a new and wider experience may bring about some alteration of these attitudes, even though by themselves they dictate nothing as to the content of experience, and no experience can conceivably prove them invalid.

Perhaps some will object to this conception on the ground that only such principles should be designated *a priori* as the human mind *must* maintain, no matter what; that if, for example, it is shown possible to arrive at a consistent doctrine of physics in terms of relativity, even by the most arduous reconstruction of our fundamental notions, then the present conceptions are by that fact shown not to be *a priori*. Such objection is especially likely from those who would conceive the *a priori* in terms of an absolute mind or an absolutely universal human nature. We should readily agree that a decision by popular approval or a congress of scientists or anything short of such a test as would bring to bear the full weight of human capacity and interest, would be ill-considered as having to do with the *a priori*. But we wish to emphasize two facts: first, that in the field of those conceptions and principles which have altered in human history, there are those which could neither be proved nor disproved by any experience, but represent the uncompelled initiative of human thought – that without this uncompelled initiative no growth of science, nor any science at all, would be conceivable. And second, that the difference between

such conceptions as are, for example, concerned in the decision of relativity versus absolute space and time, and those more permanent attitudes such as are vested in the laws of logic, there is only a difference of degree. The dividing line between the *a priori* and the *a posteriori* is that between principles and definitive concepts which *can* be maintained in the face of all experience and those genuinely empirical generalizations which *might* be proven flatly false. The thought which both rationalism and empiricism have missed is that there are principles, representing the initiative of mind, which impose upon experience no limitations whatever, but that such conceptions are still subject to alteration on pragmatic grounds when the expanding boundaries of experience reveal their infelicity as intellectual instruments.

Neither human experience nor the human mind has a character which is universal, fixed, and absolute. "The human mind" does not exist at all save in the sense that all humans are very much alike in fundamental respects, and that the language habit and the enormously important exchange of ideas has greatly increased our likeness in those respects which are here in question. Our categories and definitions are peculiarly social products, reached in the light of experiences which have much in common, and beaten out, like other pathways, by the coincidence of human purposes and the exigencies of human coöperation. Concerning the *a priori* there need be neither universal agreement nor complete historical continuity. Conceptions, such as those of logic, which are least likely to be affected by the opening of new ranges of experience, represent the most stable of our categories; but none of them is beyond the possibility of alteration.

Mind contributes to experience the element of order, of classification, categories, and definition. Without such, experience would be unintelligible. Our knowledge of the validity of these is simply consciousness of our own fundamental ways of acting and our own intellectual intent. Without this element, knowledge is impossible, and it is here that whatever truths are necessary and independent of experience must be found. But the commerce between our categorical ways of acting, our pragmatic interests, and the particular character of experience, is closer than we have realized. No explanation of any one of these can be complete without consideration of the other two.

Pragmatism has sometimes been charged with oscillating between two contrary notions; the one, that experience is "through and through malleable to our purpose," the other, that facts are "hard" and uncreated by the mind. We here offer a mediating conception: through all our knowledge runs the element of the *a priori*, which is indeed malleable to our purpose and responsive to our need. But throughout, there is also that other element of experience which is "hard," "independent," and unalterable to our will.

THE NATURE OF THE A PRIORI, AND THE PRAGMATIC ELEMENT IN KNOWLEDGE

C. I. Lewis. "The Nature of the A Priori, and the Pragmatic Element in Knowledge." *Mind and the World-Order: Outline of a Theory of Knowledge* (New York: Charles Scribner's Sons, 1929), chap. 8, pp. 230–273.

In experience, mind is confronted with the chaos of the given. In the interest of adaptation and control, it seeks to discover within or impose upon this chaos some kind of stable order, through which distinguishable items may become the signs of future possibilities. Those patterns of distinction and relationship which we thus seek to establish are our concepts. These must be determined in advance of the particular experience to which they apply in order that what is given may have meaning. Until the criteria of our interpretation have been fixed, no experience could be the sign of anything or even answer any question. Concepts thus represent what mind brings to experience. That truth which is a priori rises from the concept itself. This happens in two ways. In the first place, there is that kind of truth, exemplified most clearly by pure mathematics, which represents the elaboration of concepts in the abstract, without reference to any particular application to experience. Second, the concept in its application to the given exhibits the predetermined principles of interpretation, the criteria of our distinguishing and relating, of classification, and hence the criteria of reality of any sort. This is most clearly evident in the case of those basic concepts, determining major classes of the real, which may be called the categories, though in less important ways it holds true of concepts in general.

For both these ways in which the truth is fixed, independently of experience or in advance of it, it represents the explication or elaboration of the concept itself. *The a priori is not a material truth, delimiting or delineating the content of experience as such, but is definitive or analytic in its nature.*

The a priori as thus definitive or explicative, representing principles of order and criteria of the real, meets all the requirements which emerge from the discussion of the preceding chapter. Since it is a truth about our own interpretative attitude, it imposes no limitation upon the future possibilities of experience; that is a priori which we can maintain in the face of all experience, come what will. And although it represents the contribution of the mind itself

to knowledge, it does not require that this mind be universal, absolute, or a reality of a higher order than the object of its knowledge. The a priori does not need to be conceived as the inscrutable legislation of a transcendent mind, the objects of which, being limited by its forms of intuition, are phenomenal only. Hence the distinction of the legislative mind as ultimate reality from its object which is not thus ultimate, falls away, and with it the difficulty of knowing the mind and of recognizing what is a priori as that which is determined by our own active attitude. The a priori is knowable simply through the reflective and critical formulation of our own principles of classification and interpretation. Such legislation can be recognized as our own act because the a priori principle which is definitive, and not a material truth of the content of experience, *has alternatives*. It can be recognized as due to the mind itself by the ordinary criteria of responsibility in general – that a different mode of acting is possible and makes a discoverable difference. Where there is no possibility of refraining from our act or acting otherwise, there can be no discoverable activity – indeed, there is no act. As has been pointed out, if what is a priori sprang from a transcendent mind, acting in unalterable ways, it never could be known to be our own creation or distinguished from those facts of life which are due to the nature of the independent real. What can be known to be a priori must meet the apparently contradictory requirements that it may be known in advance to hold good for all experience and that it have alternatives. The principle of classification or interpretation meets these requirements, because the alternative to a definition or a rule is not its falsity but merely its abandonment in favor of some other. Thus the determination of the a priori is in some sense like free choice and deliberate action.

This meets also another difficulty which will already have presented itself to the reader. If the a priori is something made by mind, mind may also alter it. There will be no assurance that what is a priori will remain fixed and absolute throughout the history of the race or for the developing individual. From the point of view here presented, this is no difficulty at all but the explanation of an interesting historical fact. The rationalist prejudice of an absolute human reason, universal to all men and to all time, has created an artificially exalted and impossible conception of the categories as fixed and unalterable modes of mind. One result has been to limit the usefulness of the conception, so that what we could call, in ordinary parlance, "the categories of physics" or "the categories of biology" would not serve as examples of "the categories" because it is obvious that the fundamental principles and concepts of any natural science change progressively with its development. This, in turn, has served to obscure the large and important part played in science by that element of categorial order which cannot be determined by merely empirical fact but must be provided by the scientist himself in his setting of the problem and fixing the criteria by which the meaning of experimental findings is to be

interpreted. Thus the most impressive examples of human knowledge have been too little drawn upon in discussions of epistemology.

The assumption that our categories are fixed for all time by an original human endowment, is a superstition comparable to the belief of primitive peoples that the general features of their life and culture are immemorial and of supernatural origin. The grand divisions of our thought-world differ from those of our early ancestors as our modern machines differ from their primitive artifacts and our geographical and astronomical outlook from their world bounded by a distant mountain range or the pillars of Hercules and shut up under the bowl of the sky. Certain fundamental categories are doubtless very ancient and permanent: thing and property, cause and effect, mind and body, and the relations of valid inference, doubtless have their counterparts wherever and whenever the human mind has existed. But even here, the supposition of complete identity and continuity is at variance with facts which should be obvious.

For all primitive peoples, for example, and for some who distinctly are not primitive, the properties of a thing are not localized in time and space, as for us. Almost anything may be a talisman or fetish, whose action takes place (without intermediaries) at a distance and in a time posterior to its destruction by fire or by being eaten. Things also have doubles, inscrutably operating in that other-world whose influence mysteriously interpenetrates the realm which we call "nature." Furthermore, the long-persistent problem in physics of action at a distance increasingly comes back to haunt us and to unite with new problems of physical interpretation which threaten to drive us once more to dissipate the "material thing" throughout all time and space; to find its manifestation and even its very being in a spatio-temporal spread of events indefinitely extended.

That the present distinction of mind and body corresponds only roughly with that division in ancient thought; that body of inert matter and mind which does not occupy space are no older than the advent of that esoteric doctrine which dawned in Europe with the Greek mysteries and Christianity – this can hardly escape us. This mode of distinction contrasts with the tripartite division into body, mind, and spirit, and with the five-fold and *n*-fold divisions of more easterly cultures. It is also obvious that the pressure of modern science in the field of biology and our present uneasiness about this twofold nature of the individual, augur some departure from the clarity of Cartesian dualism.

The *names* of our categories may be very old and stable, but the *concepts*, the modes of classifying and interpreting which they represent undergo progressive alteration with the advance of thought.

Probably those modes of thought embodied in logic and in the forms of language are more fundamental than others. And very likely what we recognize as explicit categories are always superficial as compared with more

deep-lying forms which only the persistent and imaginative student can catch, in some vague and fleeting insight, because they are so nearly the marrow of our being and so all-pervasive that they can hardly be phrased in significant expression. These go back to the point where mind is continuous with the objective and indistinguishable from it. For we can know our own nature only in so far as we comprehend or vaguely imagine what it would mean to be other than we are. We can recognize the presence of mind only where mind makes a discoverable difference. If we should think of mind as what the rationalists suppose – superimposing on reality a rigid mask of form outside which mind itself could never catch a glimpse – then this altogether universal and un-get-overable form could never become self-conscious. It would remain – in Fichte's phrase – the "Great Thought which no man has ever thought." It would be not of mind but of the objective reality; it would be the Absolute which forever conditions but never can be known. But the idealistic rationalist can not eat his cake and have it too; the mind which can be recognized as such is *ipso facto* finite and limited by discoverable bounds. That mind is thus continuous with the finally mysterious – the is-ness of what is – we must of course grant; in the contemplation of mind we contemplate one aspect of the Great Fact in the presence of which all explicit thought is silenced. But the categories are not the form of that which, having no alternative and no bounds, is formless. They are the explicit bounds of that which, if it transcend them, must – fall into some other category. They are divisions within the comprehensible in general, but not the shape of comprehensibility itself.

It will be well to make clear that the conception here presented does not imply that because the a priori is something made by mind and capable of alteration, it is therefore arbitrary in the sense of being capriciously determined. That it is not, and cannot be, determined by the given, does not imply that it answers to no criteria whatever. That type of a priori truth which pure mathematics illustrates – that is, the elaboration of concepts in abstraction from all questions of particular applications – answers only to the criteria of self-consistency. Just to the extent that the development of such a purely analytic system is withdrawn from every consideration of useful application, its truth is simply truth to the original meanings embodied in its basic concepts. But when concepts are intended to be applied in experience, and a priori principles are to determine modes of classification and interpretation, the case is different. Here mind is still uncompelled by any possible content of experience. But knowledge has a practical business to perform, the interests of action which it seeks to serve. The mode of the mind's activity answers to our need to understand, in the face of an experience always more or less baffling, and of our need to control. There is also another factor which helps to determine what modes of attempted comprehension will be most easily and most widely useful. While that absolute human reason which the rationalist supposes to be completely and universally possessed by every human is a

myth, nevertheless man, being a species of animal, has characteristics which mark him as such, and some of these at least are reflected in the bent of human thought. Some modes of thought are simpler and come more naturally to us than others which still are possible and which might, indeed, be called upon if an enlarged experience should sufficiently alter our problems – just as some modes of bodily translation are more easy and natural, though these may be somewhat altered when the environment includes a sufficient number of automobiles and airplanes. Moreover, the fundamental likeness in our modes of thought, which represents whatever community of nature marks our original mental endowment, is continually enhanced by the fact that the needs of individual humans are mostly served by coöperation with others. "The human mind" is distinctly a social product, and our categories will reflect that fact.

In brief, while the a priori is dictated neither by what is presented in experience nor by any transcendent and eternal factor of human nature, it still answers to criteria of the general type which may be termed pragmatic. The human animal with his needs and interests confronts an experience in which these must be satisfied, if at all. Both the general character of the experience and the nature of the animal will be reflected in the mode of behavior which marks this attempt to realize his ends. This will be true of the categories of his thinking as in other things. And here, as elsewhere, the result will be reached by a process in which attitudes tentatively assumed, disappointment in the ends to be realized, and consequent alteration of behavior will play their part.

Confirmation of this conception of the a priori could only come from comprehensive and detailed examination of at least the major categories of thought and the underlying principles of common-sense and scientific explanation. Such a task cannot be undertaken here; at most only a few illustrations can be offered with the hope that they are typical.

The paradigm of the a priori in general is the definition. It has always been clear that the simplest and most obvious case of truth which can be known in advance of experience is the explicative proposition and those consequences of definition which can be derived by purely logical analysis. These are necessarily true, true under all possible circumstances, because definition is legislative. Not only is the meaning assigned to words more or less a matter of choice – that consideration is relatively trivial – but the manner in which the precise classifications which definition embodies shall be affected, is something not dictated by experience. If experience were other than it is, the definition and its corresponding classification might be inconvenient, useless, or fantastic, but it could not be false. Mind makes classifications and determines meanings; in so doing, it creates that truth without which there could be no other truth.

Traditionally propositions which have been recognized as analytic have often not been classed with the a priori; they have been regarded as too

unimportant; sometimes they have even been repudiated as not truth at all but merely verbal statements. The main reasons for this cavalier attitude have been two; in the first place, it has been overlooked that the real itself is a matter of definition and that the dichotomy of real and unreal is that first and basic classification which the mind confronted with experience must make. And second, the powerful sweep and consequence of purely logical analysis has not been understood.

The clearest example of this power of analysis is to be found, of course, in mathematics. The historical importance of mathematics as a paradigm of a priori truth needs no emphasis. Almost one may say that traditional conceptions of the a priori are the historical shadow of Euclidean geometry. But in mathematics much water has gone under the bridge since the time of Kant, and in the light of the changes which have come about, these traditional conceptions are proved totally impossible. The course of this development will be familiar to the reader; only the outstanding features of it need be mentioned.

Though there are anticipations of current mathematical conceptions as far back as Plato, the movement which led to their present acceptance dates principally from the discovery of the non-Euclidean geometries. In developing these systems, it was obviously impossible to depend on intuitions of space, either pure or empirical. If Euclid is true of our space, then no one of these geometries can be; and if Euclid is not true and certain, then the main ground of the supposition that we can rely on intuitions of the spatial is discredited.[1] Hence in developing the non-Euclidean systems, all constructions such as helping-lines, and any step in proof which should depend not upon pure logic but upon the character of space must be dispensed with. If a step in proof cannot be taken by rigorous logic alone, it cannot be taken at all. When it was found thus possible to develop the non-Euclidean systems without appeal to any extra-logical aids, a similar revision of Euclid was carried out, eliminating all explicit or implicit reliance upon constructions, superpositions or other appeal to spatial intuition. This new method, together with certain indicated generalizations, constituted the so-called "modern geometry."

Next it was demonstrated that not only geometry but other branches as well can be developed by the deductive method, from a relatively few assumptions, and likewise without reliance upon empirical data. As a result all pure mathematics is found to be abstract, in the sense of being independent of any particular application. Because if all the theorems follow logically from the definitions and postulates, then we can alter at will what we let the terms, such

[1] Euclid and a non-Euclidean system cannot both be true of space while corresponding denotations of terms are maintained. The discovery that they may both become true of space with systematic difference in the denotation of terms played its part in the logic of modern geometry.

as "point" and "line," denote without in the least disturbing any step in the proofs. *Whatever* "point" and "line" may mean, given these assumptions about them, these consequences – the rest of the system – must also hold of them, since the theorems follow from the assumptions by rigorous and purely logical deduction.

The question of the truth of the mathematical system *in application* was thus completely separated from its mathematical or logical integrity. Still further changes went along with this. The "truth" of initial assumptions lost all meaning in any other sense than their exhibition of certain patterns of logical relationship to be adhered to throughout. The distinguishing assumptions of a non-Euclidean geometry, for example, so far from being self-evident, were supposedly mere arbitrary falsehoods with respect to their most obvious empirical denotation. The term "axiom" was replaced by "postulate" or "primitive proposition." In the interest of logical simplicity alternative sets of assumptions which would give the same system of propositions were investigated. What should be initially assumed and what proved became a question merely of such logical simplicity. It became customary to speak of the truth of mathematics as hypothetical or to say that what mathematics asserts is only the relation of implication between postulates and theorems. It is truth about certain patterns of logical relationship established by initial definition or postulate.

Further, it became clear that the distinction between those assumptions of the form called "definitions" and those termed "postulates" was relatively arbitrary and unimportant. Logically it makes little difference except for simplicity of procedure, how far the order of a system is set up by propositions in which "is" means logical equivalence and how far by those in which it means only the one-way implication of concepts or subsumption of classes. Since the content of the concepts of pure mathematics is simply that order to which they give rise, that manner of development in which essential relationships are exhibited as the definitive meaning of the concepts is truest to the nature of the subject.

The completion of this last refinement of mathematical method was made by Whitehead and Russell in "Principia Mathematica."[2] It was here

[2] This development is still too recent for the exact bearing of its consequences to be clear in all respects. Points concerning which there may be some doubt are as follows:

(1) Can this method, without alteration, be completely carried out in geometrical branches? Some concepts needed in geometry are dealt with in volume III, but volume IV, which was to complete this subject, has not appeared.

(2) There are certain assumptions, such as the "axiom of infinity" which appear as *hypotheses* to some theorems which, apparently, require them. It is not known whether this procedure is entirely avoidable without abandoning certain classes of theorems which have their place in usual mathematical developments.

proved that the initial assumptions of mathematics can all be dispensed with, except the definitions. The truths of mathematics follow merely from definitions which exhibit the meaning of its concepts, by purely logical deduction. Judgment of such mathematical truth is, thus, completely and exclusively analytic; no synthetic judgment, a priori or otherwise, is requisite to knowledge of pure mathematics. The content of the subject consists entirely of the rigorous logical analysis of abstract concepts, in entire independence of all data of sense or modes of intuition. The definitions which embody these concepts are not required to be true in any other sense than that they should be precise and clear; the formulation of them represents an act of mind which is legislative or creative and in some sense arbitrary; it answers to no criteria save self-consistency and adequacy to whatever purposes the elaboration of the system itself may be supposed to satisfy. It may still be true that "concepts without precepts are empty," but it must be granted that there is a kind of knowledge of "empty" concepts. Or at least such admission can be avoided only by a restriction of the term "knowledge" to exclude pure mathematics and logic. The importance of such a priori analytic knowledge is witnessed by the basic character of these subjects for all other sciences.

Pure mathematics stands between logic on the one side and the empirical application of mathematics on the other. Logic is in some respects the illustration *par excellence* of the a priori, since its laws are the most completely general of any. The laws of logic cannot be proved unless they should first be taken for granted as the principles of their own demonstration. They make explicit the basic principles of all interpretation and of our general modes of classification. And they impose no limitation upon the content of experience. Sometimes we are asked to tremble before the specter of the "alogical" in order that we may thereafter rejoice that we are saved from

(3) Consistency and independence are of the essence of mathematics, since they concern its logical integrity, apart from all questions of application. It is possible to think, in view of usual mathematical procedures, that tests of consistency and independence involve implicit appeal to intuition or to applications. By the method of "Principia" it is not clear how it is possible to deal with such problems. Independence proofs have been applied to logistic systems by N. Bernays and others, but only by a reversion to those familiar devices the logic of which is precisely the point in question. Professor H. M. Sheffer has offered a general method for testing consistency and independence without reference to any possible application (See his "General Theory of Notational Relativity," privately circulated). The method of dealing with usual branches in this way must wait upon his further publication.

(4) It is questionable whether logistic methods employed in "Principia" are in all respects acceptable as "proof" and whether they do not, in certain ways, import illicit assumptions of "existence." But if there are defects of this sort, it is highly probable that they are avoidable.

this by the dependence of reality upon mind. But the "alogical" is pure bogey, a word without a meaning. What kind of experience could defy the principle that everything must either be or not be, that nothing can both be and not be, or that if *X* is *Y* and *Y* is *Z*, then *X* is *Z*? If anything imaginable or unimaginable could violate such laws, then the ever-present fact of change would do it every day. The laws of logic are purely formal; they forbid nothing but what concerns the use of terms and the corresponding modes of classification and analysis. The law of contradiction tells us that nothing can be both white and not white, but it does not and can not tell us whether black is not white or soft or square is not white. To discover what contradicts what we must turn to more particular considerations. Similarly the law of the excluded middle formulates our decision that whatever is not designated by a certain term shall be designated by its negative. It declares our purpose to make, for every name, a complete dichotomy of experience, instead – as we might choose – of classifying on the basis of a tripartite division into opposites and a middle ground between the two. Our rejection of such tripartite division represents only our penchant for simplicity and similar considerations.

Further laws of logic are of like significance. They are principles of procedure, the parliamentary rules of intelligent thought and action. Such laws are independent of the given because they impose no limitations whatever upon it. They are legislative because they are addressed to ourselves – because definition, classification, and inference represent no operation in the world of things, but only our categorial attitudes of mind.

Furthermore, the ultimate criteria of the laws of logic are pragmatic. Indeed, how could they be anything else? The truth of logic is not material truth but a truth about the modes of self-consistency. Since this is so, logic must be the test of its *own* consistency, and hence of its own truth, as well as the test of the consistency of everything else. But if logic tests its own truth, then what can be the test of truth in a genuine issue of logic, which is not a question of mere inadvertance on one side or the other? Those who suppose that there is *a* logic which everyone would agree to if he understood it and understood himself, are more optimistic than those versed in the history of logical discussion have a right to be. The fact is that, as was pointed out in the preceding chapter, there are several logics, markedly different, each self-consistent *in its own terms* and such that whoever, using it, avoids false premises, will never reach a false conclusion. Mr. Russell, for example, bases *his* logic on an implication relation such that if twenty sentences be cut from a newspaper and put in a hat, and then two of these be drawn at random, one of them will certainly imply the other, and it is an even chance that the implication will be mutual. Yet upon a foundation so remote from ordinary modes of inference the whole structure of "Principia Mathematica" is built. This logic is utterly self-consistent and

valid in its own terms. There are others even more strange of which the same may be said.[3] Genuine issues of logic are those which stand above such questions of the merely self-critical integrity of the logical system. There are such issues, and these cannot be determined – nay, cannot even be argued – except on pragmatic grounds of human bent and intellectual convenience. That we have been blind to this fact, and that much good paper and ink has been wasted by logicians who have tried to argue on some other grounds what are only questions of convenience or of value, itself reflects traditional errors in the conception of the a priori.

Pure mathematics and logic exemplify that type of the a priori which have the highest degree of abstraction from experience – whose concepts are so general that we may call them "empty." Concerning these, there may be a question whether there will not be issues of an entirely different sort when we attempt to apply them in experience. One may say, for example, that when geometry becomes abstract and freed from all necessary reference to our intuitions of the spatial, the question of the *truth about space* becomes an entirely separate one, and one with respect to which there must be reference to forms of intuition or something of the sort, or there will be nothing which is determinable a priori at all. Similarly one may say that if arithmetic as a purely abstract deductive system has no necessary reference to the character of countable objects, then its a priori truth is of no value for the anticipation of the behavior of concrete things. This will be true, of course, and of importance. If there should be a priori truth *only* with respect to concepts in utter abstraction from experience, and if this a priori character were to vanish when these concepts are given a concrete denotation, then the significance of the a priori for the natural sciences and for common practice would be largely, if not completely, lost.

But there *is* an a priori truth of concepts which have concrete denotation. Let us consider the example of arithmetic. Arithmetic depends *in toto* upon the operation of counting or correlating, a procedure which can be carried out in any world containing identifiable things, regardless of the further characters of experience. Mill challenged this a priori character of arithmetic. He asked us to suppose a demon sufficiently powerful and maleficent so that every time two things were brought together with two other things, this demon should always introduce a fifth. The conclusion which he supposed to follow is that under such circumstances $2 + 2 = 5$ would be a universal law of arithmetic. But Mill was quite mistaken. In such a world we should be obliged to become a little clearer than is usual about the distinction between arithmetic and physics, that is all. If two black marbles were put in the same box with two white ones, the demon could take his choice of colors, but it would be evident

[3] See p. 209, footnote.

that there were more black marbles or more white ones than were put in. The same would be true of all objects in any wise identifiable. We should simply find ourselves in the presence of an extraordinary physical law, which we should recognize as universal in our world, that whenever two things were brought into proximity with two others, an additional and similar thing was always created by the process. Mill's world would be physically most extraordinary. The world's work would be enormously facilitated if hats or locomotives or tons of coal could be thus multiplied by anyone possessed originally of two pairs. But the laws of mathematics would not be affected. It is because this is true that arithmetic is a priori. Its laws prevent *nothing*; they are compatible with anything which happens or could conceivably happen in nature. They are, true in any possible world. Mathematical addition is not a physical transformation. The only bringing together it implies is in the mind; if translation in general affected numerical alteration, we should always count things *in situ*, but we should count and add as usual. Physical changes which result in an increase or decrease of the countable things involved are matters of everyday occurrence. Such physical processes present us with phenomena in which the purely mathematical has to be separated out by analysis. It is because we shall always separate out that part of the phenomenon not in conformity with arithmetic and designate it by some other category – physical change, chemical reaction, optical illusion – that arithmetic is a priori. *Its laws constitute criteria of our categorial classification and interpretation.* As this example serves to illustrate, such categorial interpretation of the concrete and empirical throws out of court whatever would otherwise violate the a priori principles which embody the category, but it does not thereby legislate anything phenomenal out of existence.

Perhaps, however, we have gone too far. Mill's illustration is of an alteration of experience in general which is too simple and too poorly carried out to make it plausible that our categorial interpretation would be different in such a world. But if translation in general affected numerical alteration then an entirely different mode of categorial interpretation might better serve the purposes. Our present categories would not – *could* not – be prohibited but other modes might more simply reduce the phenomenal to order and facilitate control. Or in such a world, arithmetic might be confined to mental phenomena – since these would be exempt from the effects of change of place – and numerical principles would be laws of psychology. If we were jelly-fish in a liquid world, we should probably not add at all, because the useful purposes served by such conceptions would be so slight. Still if some super-jelly-fish should invent arithmetic by a *jeu d'esprit* (as Hamilton invented quaternions) he would find nothing in any possible experience to controvert it, and he might with some profit apply it to his own distinct ideas.

The ideal illustration of the a priori in applied geometry would be a consideration of physical relativity, showing how geometrical truth may turn upon

the place where the dividing line is drawn between the properties of *space* and those of *matter*. Applied geometrical principles are a priori true of all space-filling things. But this a priori truth has its pragmatic aspect since there are these alternatives about the manner in which the category of "the spatial" shall be bounded. But to carry out this illustration in detail would be beyond my competence.[4]

Incidentally it may be pointed out that the ideas which have gained currency through relativity-theory make clear the nature of Kant's mistakes in the supposition of a limited form of spatial intuition. For Kant, the spatial or geometrical has to do with relations of the simultaneous; the shape of a triangle, for example, is something instantaneously imaginable. But for celestial triangles, such instantaneous intuition has no meaning; what exists or happens at a distance is not directly verifiable here and now; a passage of something through time, as well as space, is inextricably bound up with the determination of the distant fact. Hence the imagination of a "curved space" need not mean something like flattening out a hemisphere without disturbing the relations of great circles on its surface. It means only imagining *certain uniform sequences* to characterize our experience of the spatial under certain conditions. The "unimaginable" character of curved space in the sense that we cannot visualize a non-Euclidean triangle on the blackboard, has nothing to do with the matter. Triangles on different scales have different "shapes" in non-Euclidean space, and triangles big enough to "verify" the nature of space are too big to "imagine." Our ancestors who believed the earth was flat could certainly "imagine" a non-Eucidean space, in the only sense which is required, since the geometry of the earth's surface is (in an obvious sense) Riemannian.

The a priori element in natural sciences goes much deeper than might be supposed. All order of sufficient importance to be worthy of the name of law depends eventually upon some ordering by mind. Without initial principles by which we guide our attack upon the welter of experience, it would remain forever chaotic and refractory. In every science there are fundamental laws which are a priori because they formulate just such definitive concepts or categorial tests by which alone investigation becomes possible.

A good example of this is to be found in Einstein's little book "Relativity."[5] The question under discussion is the criteria of simultaneity for events at a distance. Suppose the lightning strikes a railroad track at two places, *A* and *B*. How shall we tell whether these events happen at the same time? "We ... require a definition of simultaneity such that this definition supplies us with

[4] The reader may also be referred to Poincaré's "Science and Hypothesis," the section on "Space and Geometry."

[5] Pp. 26–8: italics are the author's.

a method by which ... we can decide whether or not the lightning strokes occurred simultaneously. As long as this requirement is not satisfied, I allow myself to be deceived as a physicist (and of course the same applies if I am not a physicist) when I imagine that I am able to attach a meaning to the statement of simultaneity....

"After thinking the matter over for some time you then offer the following suggestion with which to test simultaneity. By measuring along the rails, the connecting line *A B* should be measured up and an observer placed at the mid-point *M* of the distance *A B*. This observer should be supplied with an arrangement (*e.g.*, two mirrors inclined at 90°) which allows him visually to observe both places *A* and *B* at the same time. If the observer perceives the two flashes at the same time, they are simultaneous.

"I am very pleased with this suggestion, but for all that I cannot regard the matter as quite settled, because I feel constrained to raise the following objection: 'Your definition would certainly be right, if I only knew that the light by means of which the observer at *M* perceives the lighting flashes travels along the length *A–M* with the same velocity as along the length *B–M*. But an examination of this supposition would only be possible if we already had at our disposal the means of measuring time. It would thus appear as though we were moving here in a logical circle.'

"After further consideration you cast a somewhat disdainful glance at me – and rightly so – and you declare: 'I maintain my previous definition nevertheless because in reality it assumes nothing whatever about light. There is only one demand to be made of the definition of simultaneity, namely, that in every real case it must supply us with an empirical decision as to whether or not the conception which has to be defined is fulfilled. That light requires the same time to traverse the path *A–M* as for the path *B–M* is in reality *neither a supposition nor a hypothesis* about the physical nature of light, but a *stipulation* which I can make of my own free-will in order to arrive at a definition of simultaneity.' ... We are thus led to a definition of 'time' in physics."

As this example well illustrates, we cannot even ask the questions which discovered law would answer until we have first by a priori stipulation formulated definitive criteria. Such concepts are not verbal definitions nor classifications merely; they are themselves laws which prescribe a certain behavior to whatever is thus named. Such definitive laws are a priori; only so can we enter upon the investigation by which further laws are sought. Yet it should also be pointed out that such a priori laws are subject to abandonment if the structure which is built upon them does not succeed in simplifying our interpretation of phenomena. If, in the illustration given, the relation "simultaneous with," as defined, should not prove transitive – if event *A* should prove simultaneous with *B* and *B* with *C*, but not *A* with *C* – this definition would certainly be rejected.

Indeed *all* definitions and *all* concepts exercise this function of prescribing fundamental law to whatever they denote, because everything which has a name is to be identified with certainty only over some stretch of time. The definition provides criteria of the thing defined which, in application, become necessary or essential laws of its behavior. This is especially evident in the case of scientific definitions because the "things" of science are of a deep-lying sort, representing uniformities of behavior of a high order.[6] If definition is unsuccessful, as early scientific definitions mostly have been, it is because the classification thus set up corresponds with no natural cleavage and does not correlate with sufficiently important uniformities of behavior. Early attempts to reduce phenomena to law are based upon the "things" of common-sense which represent classification according to properties which are relatively easy of direct observation and impressive to the senses. When such attempts fail, it is largely because of this superficiality of initial classification. The alchemist's definitions of the elements, for example, are the clue to his indifferent success; the definitive properties pick out amorphous groups which have little significance of further uniformity. Not until such crucial properties as combining weights become the basis of classification is it possible to arrive at satisfactory laws of chemistry. The earlier definitions can not be said to have been false; they were merely useless, or insufficient to the purposes in hand. A large part of the scientific search is, thus, for *things worth naming*.

We have reached a point today where we understand that the typical procedure of science is neither deduction from what is self-evident nor relatively certain nor direct generalization from experience. If any one method is more characteristic of science than another it is that of hypothesis and verification. But we seem still to overlook the fact that the *terms* in which hypothesis and law are framed themselves represent a scientific achievement. We still suffer from the delusion that fixed and eternal categories of human thought on the one side are confronted with equally fixed and given "things" on the other. Is it not obvious, to dispassionate observation, that scientific categories and classifications are subject to progressive modification or even abrupt alteration, and that these have a directive and controlling influence upon the other phases of scientific research? And here too, as in hypothesis and verification, the development takes place, not by logical derivation from antecedent principles nor by direct formulation of empirical content, but by the hazarding of something by the mind and its retention or repudiation according to the success or non-success of what is based upon it. The test of success here is not, however, simple conformity with experience, as in the testing of hypothesis, but is the achievement of intelligible order amongst the phenomena in question, and responds also to such criteria as intellectual simplicity, economy, and comprehensiveness of principle.

[6] See Appendix A.

The reader will perhaps feel that, in so far as this is true, what is here represented as a priori is nothing of the sort but is merely something that we learn from experience. But if so, I hope that he will reread the illustration from Einstein, with due regard for the logic of it. However much the give and take between the purposes of science and discovered fact may contribute to alter the procedure by which those aims are sought, and may induce new basic principles and categories, still the naming, classifying, defining activity is at each step prior to the investigation. We cannot even interrogate experience without a network of categories and definitive concepts. Until our meanings are definite and our classifications are fixed, experience cannot conceivably determine anything. We must first be in possession of criteria which tell us what experience would answer what questions, and how, before observation or experiment could tell us anything.

The uniformities which science seeks are of a high order and represent a further reach of those same purposes exhibited on a humbler scale by the uniformities of common sense comprehension. The categorizing and classifying activity of thought is, thus, more deliberate and self-conscious in the case of science and, by comparison, easier to observe than in the case of common sense. Because scientific categories are in some part built upon more basic distinction, the functioning of them as criteria of the real is less frequent and perhaps less important. It is, nevertheless, sometimes to be observed in the interplay between new principles of scientific interpretation and residual phenomena which are unexplained or reports of observation which are regarded as possibly involving error. If Röntgen had been unable to repeat the experience in which he first saw the bones of his hand, that perception would have been discredited. Because no one but their discoverer could see the "N-rays" with any assurance, and it was found that he saw them when the refracting prism was removed as well as with it, they were discarded as illusory. The phenomena of hypnotism remained for a long time in the limbo of the dubious, and even today offer a difficult problem of separation of veridical phenomenon from illusion, self-deception and the like. The phenomena of "dual personality" would challenge a very fundamental category if only there were not so much doubt about what it is that is "dual" and whether it is genuinely dual. To choose a different sort of example when the eclipse-photographs which figured in the discussion of relativity were examined, the question was raised whether the star-displacements as measured on them represented simply the bending of light-rays or were due in part to halation of the sensitive film. Thus, for a moment at least, so fundamental a problem as that of abandoning the categories of independent space and time was intertwined with the question whether the position of dots on a photographic plate represented authentic star-photographs or was due to something which took place inside the camera.

What needs to be observed here is at once the continuity of scientific problems of a high order with the apparently simple and fundamental criteria of the real, and the fact that such decisions of reality or unreality are themselves interpretations involving principles of the same order as scientific law. They are such as forbid, for example, the non-biological transformations and non-physical successions which occur in dreams. A mouse which disappears where there is no hole, is no real mouse; a landscape which recedes as we approach, is but illusion. The reality of an object of a particular sort is determined by a certain uniformity of its behavior in experience. The formulation of this uniformity is of the type of natural law. So far, such laws are a priori – for this particular sort of thing; the experience which fails to conform to the law is repudiated as non-veridical.

This situation is most paradoxical; principles of the order of natural law are reached by some generalization from experience – that is, from *veridical* experience; there are no generalizations whatever to be had from the unsorted experience of real and unreal both. But what experience is veridical, is determined by the criterion of law. Which is first, then; does the content of experience validate the law or does the law validate the experience in attesting its veridical character? The answer is that the law is first precisely so long as and so far as we are prepared to maintain it as criterion of the real. But the "reality" which is in question is likely to be of a highly specific sort. The authentic photograph of stars and the picture affected by halation, for example, are both real, both physically real, both photographs even, in a certain sense. What is an "authentic photograph" has to be very precisely defined in the case in point and is so defined as to exclude the effect of light reflection from the back of the glass of the photographic plate. The manner of this definition or classification obviously will require a correlation of photograph and thing photographed of the type set forth in certain physical laws. In the particular case, failure to exhibit such lawful relationship condemns the phenomenon as not authentic or not real – that is, not really this very specific sort of thing.

Thus all concepts, and not simply those we should call "categories," function as criteria of reality. Every criterion of classification is criterion of reality of some particular sort. There is no such thing as reality in general; to be real, a thing must be a particular sort of real. Furthermore, what is a priori criterion of reality in one connection may be merely empirical law in some other – for example, the law correlating photograph and thing photographed, or the law of the behavior of solid bodies in translation which condemns the mouse that disappears without a hole, or the laws of perspective which exclude a landscape which recedes as we approach it. *The determination of reality, the classification of phenomena, and the discovery of law, all grow up together.* I will not repeat what has already been said so often about the logical priority of criteria; but it should be observed that this is entirely

compatible with the shift of categories and classifications with the widening of human experience. If the criteria of the real are a priori, that is not to say that no conceivable character of experience would lead to alteration of them.

For example, spirits cannot be photographed. But if photographs of spiritistic phenomena taken under properly guarded conditions, should become sufficiently frequent, this a priori dictum would be called in question. What we should do would be to redefine our terms. Whether "spook" was spirit or matter, whether the definition of "spirit" or of "matter" should be changed; all this would constitute one interrelated problem.

What would prove to you that the relative motion of a body effected a foreshortening of it and altered its mass? If the answer is "no conceivable experience" and you are able to formulate a definition of "mass," a conception of motion, and of ideally exact measurement in terms that do not conflict with one another and with your other physical conceptions, there is no possible ground on which you could be proven wrong. To a mind sufficiently resolute for an independent space and time, no possible experience could prove the principles of relativity. The question, "How long shall we persist in holding to our previous categories, when confronted with star-photographs and the displacement of spectrum-lines (or with spiritistic phenomena or evidence of telepathy) ?" is one which has no general answer. A stubborn conservatism can be proved unreasonable only on the pragmatic ground that another method of categorial analysis more successfully reduces all experience of the type in question to order and law. Confronting such a problem, we should reopen together the question of definition or classification, of criteria for this sort of real, and of natural law. And the solution of one of these would probably mean the solution of all. Nothing could *force* a redefinition of "spirit" or of "matter." A sufficiently fundamental relation to human bent or to human interests would guarantee continuance unaltered even in the face of unintelligible and baffling experience. And no equipment of categories and concepts which the mind is likely to achieve will enable us to understand experience completely and in every respect. In such problems, the mind finds itself uncompelled save by its own purposes and needs. What is fixed datum and must be conformed to, is only that welter of the given in which not even the distinction of real and unreal is yet made. The rest is completely and exclusively our problem of interpretation. I *may* categorize experience as I will; but what categorial distinctions will best serve my interests and objectify my own intelligence? What the mixed and troubled experience will be – that is beyond me. But what I shall do with it – that is my own question, when the character of experience is before me. I am coerced only by my own need to understand.

It would indeed be inappropriate to characterize as a priori a law which we are prepared to alter in the light of further experience even though in an isolated case we should discard as non-veridical any experience which failed

to conform. But the crux of the matter lies in this; beyond such principles as those of logic and pure mathematics whose permanent stability seems attested, there must be further and more particular criteria of the real prior to any investigation of nature. Such definitions, fundamental principles and criteria the mind itself must supply before experience can even begin to be intelligible. These represent more or less deep-lying attitudes, which the human mind has taken in the light of its total experience up to date. But a newer and wider experience may bring about some alteration of these attitudes even though by themselves they dictate nothing as to the content of experience, and no experience can conceivably prove them invalid.

It is the a priori element in knowledge which is thus pragmatic, not the empirical. The pragmatists generally have neglected to make the separation of concept and immediacy, with the result that they seem to put all truth at once at the mercy of experience and within the power of human decision or in a relation of dependence upon the human mind. But this would be an attempt to have it both ways. The sense in which facts are brute and given cannot be the sense in which the truth about them is made by mind or alterable to human needs. To be sure, this a priori element in knowledge runs very deep; it is present whenever there is classification, interpretation, or the distinction of real from unreal – which means that it is present in all knowledge. So I suppose it must be admitted, in the last analysis, that there can be no more fundamental ground than the pragmatic for a truth of any sort. Nothing – not even direct perception – can force the abandonment of an interpretive attitude, nor indeed *should* move us to such abandonment (since illusion or mistake is always possible) except some demand or purpose of the mind itself. But certain important ends, such as intellectual consistency and economy, completeness of comprehension, and simplicity of interpretation, occupy a place so much higher, for the long-run satisfaction of our needs in general, that they rightfully take precedence over any purpose which is merely personal or transitory. In the popular mind especially, pragmatism too often seems to connote the validity of rather superficial and capricious attitudes – for instance, the justification of belief from no deeper ground than personal desire. It is this insufficient regard for intellectual integrity, this tendency to trench upon high-plane purposes from low-plane motives which marks the kind of "pragmatism" which is to be eschewed. We must all be pragmatists, but pragmatists in the end, not in the beginning.

In another respect also, there is a connotation of "pragmatism" which more or less prevails, which is inapplicable to the theory here presented. Concepts and principles of interpretation are subject to historical alteration and in terms of them there may be "new truth." But the situation in which this happens needs analysis. It does not mean the possibility of new truth in any sense in which new truth can genuinely contradict old truth. This may not at first be clear. New ranges of experience such as those due to the invention of the

telescope and microscope have actually led to alteration of our categories in historic time. The same thing may happen through more penetrating or adequate analysis of old types of experience – witness Virchow's redefinition of disease. What was previously regarded as real – *e.g.*, disease entities – may come to be looked upon as unreal, and what was previously taken to be unreal – *e.g.*, curved space – may be admitted to reality. But when this happens *the truth remains unaltered and new truth and old truth do not contradict.* Categories and concepts do not literally change; they are simply given up and replaced by new ones. When disease entities give place to mere adjectival states of the organism induced by changed conditions such as bacteria, the old description of the phenomena of disease does not become false in any sense in which it was not always false. All objects are abstractions of one sort or another; a disease entity is found to be a relatively poor kind of abstraction for the understanding and control of the phenomena in question. But in terms of this abstraction any interpretation of experience which ever was correctly made will still remain true. Any contradiction between the old truth and the new is *verbal only*, because the old word "disease" has a new meaning. The old word is retained but the old concept is discarded as a poor intellectual instrument and replaced by a better one. Categories and precise concepts are logical structures, Platonic ideas; the implications of them are eternal and the empirical truth about anything given, expressed in terms of them, is likewise through all time unalterable.

In the typical case in which old methods of interpretation are discarded in favor of new ones, it requires new empirical data, which offer some difficulty of interpretation in the old terms, to bring about the change. Any set of basic concepts has vested interests in the whole body of truth expressed in terms of them, and the social practices based upon them. The advantage of the change must be considerable and fairly clear in order to overcome human inertia and the prestige of old habits of thought. Such new and recalcitrant data, which bring about the change, complicate the problem of comparing the "new truth" with the old. The factors which need to be considered are: (1) the two sets of concepts, old and new, (2) the expanding bounds of experience in which what is novel has come, to light, (3) the conditions of the application of the concepts to this new body of total relevant experience.

In the case of the Copernican revolution, for example, it was the invention of the telescope and the increasing accuracy of observation which mainly provided the impetus to reinterpretation. But these new data were decisive only in the pragmatic sense. Those who argued the issue supposed that they were discussing a question of empirical fact. But since there is no absolute motion, the question what moves and what is motionless in the heavens is one which cannot be settled by experience alone. The fixed stars prove to be a highly convenient frame of reference, resulting in relatively simple generalizations for the celestial motions, and enabling celestial and sublunary

phenomena to be reduced to the same equations, while almost insurmountable complexity and difficulty attend the choice of axes through the earth. Theoretically, however, if any system of motions is describable with respect to one set of axes, it is also describable in terms of any other set which moves with reference to the first according to any general rule. Let us imagine for a moment that this theoretically possible description of astronomical and physical phenomena in terms of a motionless earth had been worked out for all the data now at hand. In terms of which set of concepts, old or new, should we have the truth? Obviously in both. The one would be comprehension and simple truth; the other so complex as to be almost or quite unworkable. But they would no more contradict each other than a measurement in pounds and feet contradicts one in grams and meters.

This situation is not altered by any thought that newly discovered fact may play another than the pragmatic rôle and be decisive of truth in a deeper sense. Nobody has ever supposed that what were only hypotheses or empirical generalization of a high degree of probability were incapable of being disproven by new facts. To the extent that newly discovered empirical evidence may render old principles theoretically impossible, the old truth never was anything but hypothesis and is now proved flatly false. It is not, I hope, the point of the pragmatic theory of knowledge to reduce all truth thus to hypothesis. That would be nothing but a cheerful form of skepticism.

Rather the point of the pragmatic theory is, I take it, the responsiveness of truth to human bent or need, and the fact that in some sense it is made by mind. From the point of view here presented, this is valid, because the interpretation of experience must always be in terms of categories and concepts which the mind itself determines. There may be alternative conceptual systems, giving rise to alternative descriptions of experience, which are equally objective and equally valid, if there be not some purely logical defect in these categorial conceptions. When this is so, choice will be determined, consciously or unconsciously, on pragmatic grounds. New facts may cause a shifting of such grounds. When historically such change of interpretation takes place we shall genuinely have new truth, whose newness represents the creative power of human thought and the ruling consideration of human purpose.

The separation of the factors, however, reveals the fact that the pragmatic element in knowledge concerns the choice in application of conceptual modes of interpretation. On the one side, we have the abstract concepts themselves, with their purely logical implications. The truth about these is absolute, in the fashion in which pure mathematics offers the typical illustration. Such purely abstract a priori truth answers only to the criteria of consistency and adequacy. It is absolute and eternal. On the other side, there is the absolute brute-fact of given experience. Though in one sense ineffable, yet the given is its own fashion determinate; once the categorial system, in terms of which it is to be interpreted, is fixed, and concepts have been assigned a denotation

in terms of sensation and imagery, it is this given experience which determines the truths of nature. It is between these two, in the choice of conceptual system for application and in the assigning of sensuous denotation to the abstract concept, that there is a pragmatic element in truth and knowledge. In this middle ground of trial and error, of expanding experience and the continual shift and modification of conception in our effort to cope with it, the drama of human interpretation and the control of nature is forever being played. That the issues here are pragmatic; that they do not touch that truth which still is absolute and eternal – this is the only thing that would save those who appreciate the continually changing character of this spectacle from skepticism.

EXPERIENCE AND ORDER

C. I. Lewis. "Experience and Order." *Mind and the World-Order: Outline of a Theory of Knowledge* (New York: Charles Scribner's Sons, 1929), chap. 11, pp. 345–391.

Since empirical knowledge is exclusively knowledge of probabilities, the validity of it in general depends upon the validity of induction and probability-judgment. The preceding chapter has been written as if some principles of such inference may be presumed as valid. That presumption, however, requires justification, particularly since the grounds upon which it is often supposed to rest have here been repudiated. Let us phrase the issue as sharply as possible: Concepts are of the mind. All knowledge is in terms of concepts, and the possibility of it depends upon their applicability to experience. The application of a concept requires always a certain orderly sequence in experience. But the content of experience is independent of the mind; that order is discoverable in possible experience, cannot be dictated by the knower. If generalization is to be possible – if concepts are to be applicable in distinguishable classes of cases, and if the connection of concepts in such generalizations is to find its application in reality – then the givenness of certain qualia, or complexes of such, must be a clue to expected sequences, and the occurrence of such sequences in the past must be a ground of their valid prediction for the future.

However, it is *not* requisite that such expectation and predication should be *certain*. Knowledge of particular objects is never beyond the possibility of mistaken apprehension; and empirical generalizations are, theoretically, never more than highly probable. What is requisite, then, in order that empirical knowledge should be valid, is that this connection of given qualia with expected sequences, and the connection between the sequences prescribed by one concept and that which is essential to some other, should be genuinely probable. In general there must be the possibility of arguing from past to future; not with certainty, but with probability.

Concerning probability-judgments, it has been pointed out, first, that their validity does not require that what is judged probable should be true – not even that the particular generalization should be true of any specifiable proportion of actual cases. Second, the probability-judgment is relative to the pertinent knowledge of him who makes it; and this relativity is no bar to its validity. Third, this relativity of the probability-judgment to its premises

means that its validity, in the particular instance, consists in a certain relation between the conclusion and its ground; and means also that if it is valid it is true, absolutely and eternally. These three characters of probability-judgments rest upon obvious facts which cannot be denied without destroying the distinction between probability and certainty. It is an immediate consequence of them that a particular empirical judgment, if it represents a probability-inference justly drawn from its grounds, is absolutely true knowledge. The one remaining question is whether there are any valid principles of such inference according to which a particular empirical judgment may be justly drawn. If probability-judgment *in general* may be valid then there is no further ground of doubt that empirical judgments which are rational are true.

For the ideal completion of the argument, presentation and detailed examination of the principles of probability-inference and induction – as well as of our categorical concepts – would be in order. But the reader will not ask for that in the present book – another of at least equal length would be required. The particular ground of possible doubt is obvious enough: the applicability of concepts and the argument from past to future, require the presence of some order and uniformity. In an experience whose content is independent of the mind, it may be thought that such order could conceivably be lacking, and that the presumption of it is, therefore, dogmatic and without foundation. Pointing out that the validity of probability consists in a relation between the conclusion and its ground, and that the truth of what is judged probable is not directly relevant, does nothing to meet this present point. Precisely what is in question is whether a judgment which is in this sense subjective, confronting an experience which is independent, can be meaningfully relevant to the constitution of reality.

Since the applicability of concepts (or recognition of things by their appearances) as well as the validity of generalizations, is in question, the issue concerns the intelligibility of experience as well as the possibility of empirical knowledge. These two turn, for the most part, upon the same considerations.

The conclusion of which I shall hope to convince the reader is that no assumption of anything which could conceivably be false is necessary; that no sort of experience which the wildest imagination could conjure up could fail to afford a basis for intelligibility and probable judgment. The contrary assumption has frequently been due to the false conception that is *certainty* of apprehension and certainty of generalization which must be provided for. And some of those same confusions which we have found surrounding previous issues are involved here also.

I recognize that my burden of proof in this matter is a heavy one. Belief in something meant by the "uniformity of nature" is, I think, as natural to us as belief in an absolute up and down, and is supported by many habits of thought which are fundamental and pervasive. And so far as I know, it has never up till now been questioned, except by those who willingly faced a

skeptical alternative. In a sense, this belief is not to be questioned here, but rather whether it has any alternative at all; the precise problem is, perhaps, just what is involved in the necessary "uniformity." In this difficult situation, instead of proceeding directly to the center of the problem, I wish to begin with a variety of more peripheral considerations. Perhaps if a sufficient number of external buttresses are removed, the false conception will fall of its own weight.

Two points which are immediately relevant to the question of order in reality can be brought forward from what precedes; first, that reality and the content of experience are not directly synonymous, and second, that our categories are so divided that always we play a sort of game of "animal, vegetable, or mineral" with the given. It is reality, not experience, which must be orderly. Failure of a certain type of order is the criterion which excludes the given from reality (of a certain type). Thus so far as any one category is in question, our method of understanding experience is to segregate, as "reality," that part which is orderly in the required fashion; the rest is understood by being labeled "unreal." With this in mind, our rational demand that reality shall be orderly somewhat reminds one of the silly old story we used to tell as boys of the man who made a list of those he could whip: when a neighbor whose name was included belligerently affirmed, "You can't whip me," the maker of the list replied, "All right; then I'll just rub your name off." Experience has not much chance to thwart our demand for order when the failure to be orderly in certain ways merely results in its being rubbed off the list of that which it is demanded shall be thus orderly.

To be sure, what is excluded from one category must be brought under some other if it is to be intelligible. But any set of coördinate categories is simply a method for exhausting the possibilities. The "unreal" is a temporary pigeon-hole for what requires be sorting or analyzing in some further fashion. The unsatisfactoriness of such a scrap-basket category merely reflects this desirability of a further understanding of its content. But to be able to classify what is presented as "unreal" or "illusion," though it may represent only superficial understanding, means nevertheless a very important understanding, precisely because it means that this content of experience is not relevant in the present connection that it cannot figure as a negative instance of an empirical generalization and so on. So far, then, the reality presented to us in experience is certain to be intelligible and orderly, because the failure to make a certain kind of sense merely results in its being relegated to the box we keep for pi. The only question is, *how much* of experience will be reality, and how much illusion. It will be obvious that this depends, in part, at least, upon the intellectual ingenuity of the knower – his power, when some expected order fails, to discover some other which is definite to like degree. It is further clear that to the question, "How .much of given experience will be illusory?" there can be no a priori answer.

In this connection it is well to remark that our understanding of the given is always a matter of degree, and that the order demanded of reality is, similarly, more or less specific. If there is any sense in which the real must be "through and through" orderly, at least such through and through order is an ideal correlated with that "complete understanding" which is impossible to any but an absolute mind. And there must be some other sense in which predictable order is *not* demanded of the real. The reasons for this will bear a little investigation.

I find this morning on my study window a number of apparently random grayish smudges. The explanation promptly comes to mind; small children played here yesterday. Just this pattern of smudges probably never occurred before and never will again. But this failure to exhibit any definitely anticipatable arrangement excites no surprise; it is just what one expects of children's finger marks. This superficiality of our demand for order reflects, in part, the lack of any further cognitive problem. If my choicest possessions were all missing this morning, I should ask for something more. The detective would come in and, starting from a system which exhausts in certain ways the possibilities of finger-marks, would seek to establish a correlation identifying a thief. But even so, these finger marks would still fail to be uniform with anything else in *some* ways in which order could exist and might be expected. The phrase "through and through" as applied to the uniformity or order demanded of reality is rather vague.

It also suggests itself that, in the process of our learning the nature of the real, what we do is to look for *some* order of a certain general type and, if we do not find that, to look for some *other*. The first attempt at uniformity may be, for example, that sparks fly upward, water runs down hill and "Everything seeks its natural level." Balked in this, a second attempt is, "Bodies fall in proportion to their weight." Finally we have $v = g\,t$. The point here is not simply that one attempted generalization having failed, we seek another. It is that the type of uniformity first sought – a correlation between gravitational behavior and physical kinds – does not exist. Nor is there any correlation with weight. The correlation found between velocity and time is of an entirely different sort. Not order "through and through" but *some* order is what is requisite to intelligibility. And in the light of the nature of our learning process, the dictum "There must be some order in any given area of reality" takes on the character of a regulative principle, not particularly different in significance from, "If at first you don't succeed; try, try again." More explicitly and accurately, the situation may be stated thus: A certain minimal order is prescribed a priori in the recognition of the real. It is a regulative maxim of reason to seek further uniformities which may be stated in principles finally of maximal comprehensiveness and simplicity. But there neither is nor can be any prescription of the specific type of uniformity or correlation which is demanded in this interest of further intelligibility.

Moreover, the particular kind of order discoverable in one segment of the real may be definitely absent in some other segment in which it might with equal reasonableness be anticipated.

The situation is entirely comparable if we turn from the kind of uniformity necessary for generalization to the kind which is essential for the recognition of objects. A certain minimal uniformity is prescribed by the categorical classification as reality of a certain type. Further uniformity may be sought for the purpose of further classification. But the manner in which such further uniformity shall be found is not determinable – unless by some scheme of subordinate categories, exhausting the possibilities in a particular way – in advance of familiarity with the area of reality which is in question. Nor can it rationally be "demanded" that any particular degree or kind of such uniformity shall be always exhibited by experience which is intelligible. What the recognition of objects requires is some correlation between given appearance and that sequence with further experience which is requisite to identification and to discrimination of veridical from mistaken apprehension. But it cannot be required for the intelligibility of experience that within the limits of the *given* there must be that which affords the basis of such uniform correlation. If within every empirical content merely as given there were that which possessed absolute uniform correlation with that further sequence which is essential to a correct apprehension, then illusion and mistake would be possible only to the inexperienced and the fool. It is true that only the irrational need be, in the strictest sense, deceived by appearances; but this is because the rational must realize that mistaken apprehension is always possible and identification in general are only probable. The possibilities of sequence between the appearance and further experience must be at least dual wherever the experienced and intelligent observer finds even the slightest possibility of mistaken apprehension. Obviously it is not the case that every given quale or every complex of such has some uniform correlation with something else, sufficient to render it intelligible in the manner knowledge seeks, else we should all of us stand convicted of stupidity to a degree which is quite implausible.

There is another way in which it can be made evident that we cannot require that experience, in order to be intelligible, must be such that something in the given content of any experience is uniformly followed by something else in further experience. If this were the case, then within every experience merely as given must be something which determines absolutely this further experience which is predictable from it. This further experience, in turn, would likewise dictate some future experience, and so on. Thus any given experience would uniquely determine the course of future experience, or at least of some endless chain of further experiences. It may seem that this is precisely what *is* required for knowledge and prediction. But it is not: in a world so constituted whatever could be learned would not be worth knowing,

because nothing could be done about it. It is worth learning that hot stoves burn precisely because the feeling of radiated heat does *not* inevitably determine that further sequence which we first investigated to our cost, but only determines it *under certain further conditions* which we take care not to allow. There *is* a uniformity in *reality* – hot things burn – which is definable as a uniformity of *possible experience*. But the antecedent in terms of which the consequent, being burned, is determined, is something much more complex than what is confined within the given experience of radiated heat. Otherwise we should fatally go on to be burned every time we felt it, just as we did at first. Now *some* things, which are predictable, are doubtless unavoidable in experience. But even in these cases; it does not necessarily follow that they are determined consequents of given experience. It is possible – and much more likely – that here too the antecedent of which they are uniform consequents is something much larger and more complex than any previous given experience. Often our inability to avoid them is due to our ignorance of the further conditions, beyond our experience, upon which these consequents follow. If we knew enough, we could still avoid them, and that is the agony of our situation. And often also – if not universally – where some future experience is beyond our power to avoid, and would still be beyond our power even if our knowledge should be greater, it is nevertheless the case that the determining antecedent is not wholly within our experience but contains further conditions outside it but also outside our capacity to change. If it were not for these further conditions, we might still have precisely this experience and yet escape the dénouement. Quite clearly then, knowledge does not require that kind of uniformity which would mean that something given in experience is uniformly followed by something further in experience. If this were so, then life – so far as we could know and understand – would be merely a fatal unfolding of the inevitable, and our knowledge would be a worthless revelation of that fate. Even those who read life and reality in terms of such inevitable unfolding, do not condemn us to foresee it step by step merely through intelligent inspection of our given experience. As has been pointed out, those predictions which are the primary constituents of our useful knowledge of nature are of the form: Since *X* is given, if condition *Y* should be supplied, then *Z* would accrue. Where *Y* is a condition which I myself fulfill, or refrain from fulfilling, my knowledge serves to guide my action to desired ends. The sweetness of the apple, the hotness of the stove, etc., are known by means of such truth of hypothetical propositions: this round, ruddy somewhat being given, if I should bite, it would taste sweet; this visual presentation and feeling of warmth being given, if I should touch, I should be burned. As has been pointed out, if I could *do* nothing about experience, then since such hypotheticals would be meaningless, reality would be no thicker than an inevitable stream of consciousness – that is, I should not confront *reality* but at most only a fatally determined life. Knowledge of

reality serves for the control of *experience*: without the possibility of control, not only would knowledge be worthless; there would be for us no reality to know. Both the usefulness of knowledge and the meaningfulness of reality require that the uniformity apprehended by knowledge should not be such that the determining antecedent is completely contained in the experience now fixed by being given. It is required for the significance of knowledge and the real that uniformities be specifiable – as probable at least – in terms of *possible* experience. But between possible and actual experience is the whole of that which differentiates reality from mere immediacy. Whatever the uniformity of reality required for knowledge may mean, it *cannot* mean a fixed and uniform sequence in which given experience is one complete term.

It is further to the point that the whole effort of intelligence and those habits of action which are presumably its genetic antecedents, are bent to the apprehension of whatever in the given may constitute a distinguishing mark and serve the purpose of prediction. The instant mental reaction to experience, the manner in which we approach it and the way in which we abstract from it the presentation of objects, reflect millennia of nature's work to the end that we may grasp whatever in experience is clue to some uniformity of the sort which intelligibility requires. Such characters of the given arrest the attention and are for us *something*, while that which does not thus possess meaning slides off the surface of the mind; it requires a reversal of all that is natural and habitual for us to catch it, and there is no word by which it may be held. Hence it is almost inevitable that the extent to which actually given experience is uniform or contains clues to uniformity, should be exaggerated to our casual inspection.

There is another consideration which should be added to this. It is a rational demand, of at least as good standing as the demand for uniformity, that every individual object shall be unique. Such uniqueness cannot reside in the given appearance of the thing: the number of sensory qualia we can distinguish is finite, and the number of combinations and arrangements possible within the mental field of a single experience, though large, is totally inadequate to uniqueness. This uniqueness can only reside in the further specifiability of the object in possible experience continuous with the appearance of it; that is, in something which is true about the object, though it is not at this moment apparent, and something which, by appropriately directed investigation, we could learn. Hence this demand for uniqueness requires that every recognizable appearance must be correlated with some further verifiable specification of the object, in a way which is different in at least some one respect from each and every other. When the multiplicity of objects, actual and conceivable, is contemplated, it becomes clear that the extent to which experience is thus required to be non-uniform is indefinitely large.

I do not here defend the theoretical consistency of such conception of uniqueness, and I do not accuse any one of holding to it in this form; any more

than I would attribute the theory of "through and through" uniformity to anybody in particular. My object is to let one shibboleth fight another, to the end that certain vague and unexamined modes of thought may be dragged into the light and certain superstitious and equally vague beliefs about experience may be destroyed. The most that can reasonably be believed is that experience when caught in the net of our categories, will always afford *some* clue to an actually existent further uniformity of some sort. Identifiable or recognizable appearances in their continuity with further experience, must be at least as much *non*-uniform as uniform.

A further simple illustration of the way in which non-uniformity may be remarked and yet have no significance for knowledge, may be of service. There is a popular superstition that no two snow crystals ever exhibit precisely the same pattern. I have no idea what warrant there is for it, and perhaps the reader has not either. We can see that the number of possibilities of such crystalline forms is indefinitely large, but within the limits of size and of the smallest discernible element, it would be finite. Suppose that neither general uniformity nor uniqueness should obtain. Nothing in this would be baffling to our recognition of snow or our knowledge about it. Whether this illustration really serves or not, at least nature is full of such – frost-patterns, the leaves of trees, the structure of growing plants, etc. Yet those relatively slight and superficial ways in which two oak-leaves or two frost-patterns are alike, suffice for our recognition of them and our generalizations about them. A non-uniformity, to be significant for knowledge, must be very specific – it must be a negative instance of our predictive recognition or attempted generalization. And even when we are thus thwarted, we simply give up our previously held specific mark or law, and proceed to understand that kind of object *in some other way*.

Quite frequently that order which intelligibility and law require has to be sought at some one level and escapes us at other levels. A general illustration is the whole body of those phenomena recognized by science in which macroscopic uniformity is superimposed upon microscopic multifariousness. That law at the macroscopic level may even be based upon an assumed randomness of the microscopic, is instanced by the kinetic theory of gases. As is well known, it may be held that law in general has this character. Whether this theory of law as statistical generalization of random distribution at some lower level is defensible or not, at least it is of great importance that the absence of observable order which is called "chance" itself becomes a kind of uniformity and may give rise to law.

This type of consideration is, it seems to me, an observation about our modes of dealing with phenomena rather than about nature or experience. There are other types of illustration also of the fact that certain kinds of order are imposed where none is directly observable. The outstanding example is, of course, arithmetical order, which presumes nothing more than some kind

of identifiably. I do not refer here to the counting of assemblages; important though that may be, still it is less important than the serial arrangements imposed upon intensive (that is, qualitative) differences. At least I believe that this is what examination of our categories would reveal. The multiple types of such "arrangements" of what is in no sense arranged in nature or experience – either before or after – will need no comment; nor will the fact that such imposed order quite generally provides the basis in terms of which other types of order are expressed.

At the risk of going beyond what could be clear without detailed examination of our categories, I would draw attention to two characteristics of such imposed order.[1] In the first place, it allows an infinite multiplicity to be brought under a finite simplicity of rule. It may seem trivial to remark that ten characters and a rule of adding 1 give us command of infinity, but without that, or something similar, there would be no point in counting – though there might be in serial arrangement. And second, correlation between numerical order and an imposed serial arrangement of qualities extends the power of this type of order to what is in no sense countable. Such imposed order, which demands no sort of uniformity of nature beyond the persistence of identifiable characters, is at least a prime constituent of intelligibility, though without some sort of correlation between it and that further kind of order which means determinable sequence of experience, it would not possess the significance which it does.

This type of correlation can be illustrated by the case of color. The distinguishable color-qualia are not unlimited in number but are confusingly numerous, and also they are subject to the accident of indiscernible difference; *B* may be indistinguishable both from *A* and from *B*, though *A* and *C* are recognizably different. We make a virtue of this difficulty by translating the *A*–*B*–*C* qualia as a continuous series. The manner in which this procedure is systematically carried out, in the color-pyramid, needs no exposition here. It should be noted that this arrangement would permit of algebraic treatment, quite independent of any correlation between color and harmonic motions, which is a *further* order, of the type of discovered generalization.

Color also illustrates another common method of achieving simplicity; that is, by dividing a whole field of qualia into classes by the use of names with a qualitative range of denotation. "Red" or "blue" represents no single quale, but instead a considerable variety of such. That the mind could hardly make a beginning of bringing order into given experience without this device, should be evident. It is made use of wherever it is the case that no imaginable instance can completely contain or illustrate the essential denotation of the concept – as there can be no image of triangle in general or dog in general.

[1] It will occur to the reader that, according to Cassirer, such dimensional and serial arrangement is the *universal type* of conceptual order.

This assignment to a name of a range of denotation should be sharply distinguished from that abstraction of the essential and ignoring of other characters which is represented by many theories as the universal basis of general names. Such theories are, of course, inadequate in several ways.[2]

The substitution of simple classification based on resemblance for an indeterminately large number of distinguished qualia, is of considerable importance in connection with probability-judgments. For instance, there is a finite probability that this book will be bound in red, because it must be bound in red, orange, yellow, green, blue, purple, black, white, or gray, if it is bound at all. The determinable probability arises through the fact (among others) that, within the universe of discourse in question, the possibilities are exhausted by a definite number of categories.

It is evident that the last few pages have touched superficially upon a variety of topics relative to the categories, each of which is worthy of extended examination. But as has been said, these matters are not of central importance to the main issue. The points which I hope have been suggested, if not established, are the following: Reality is more orderly than experience, because reality is experience categorized. Lack of certain types of anticipated order leads to repudiation of the given content as "unreal." The "unreal" must be capable of being understood – in some other way – but understanding is always a matter of degree, and the designation "unreal" ordinarily marks that type of superficial understanding which characterizes the situation in which it is important only that a particular given experience be excluded from the field or what is relevant to the problem in hand. All generalizations are based upon reality, not upon uncategorized experience. Neither reality, or nature, nor experience is orderly in the sense that what is presented may be taken in any way we please and found to exhibit uniformity with other instances. Intelligibility does not require such "through and through" uniformity but only *some* uniformity. What such uniformity shall be, we do not dictate to experience, save that specific kinds are requisite to subsumption in particular categories. Beyond that, the rational demand for uniformity wears somewhat the appearance of regulative ideal, or maxim for the conduct of investi-

[2] The real basis of classification of the kind in question is, of course, similarity. Similarity is of two types, partial identity and resemblance proper. A spatial or temporal whole, like a contour or a melody, may be divisible into parts some of which may be qualitatively identical. But similar color-qualities are an instance of the other type. Resemblance means the possibility of confusion. It is apprehended by conscious or unconscious recognition of this possibility. A man "looks like" my brother if, at a quick glance or at a distance, I might mistake him for my brother. Things are more or less similar according as optimum conditions must be more or less nearly approached for distinction to be made. Partial identity may also be included under this rubric. It should be noted that recognition of similarity is a kind of latent generalization.

gation. Intelligibility and understanding are not incompatible with irreducible variety; such lack of uniformity may be irrelevant to the particular mode of cognition. Further, we seem to have a theoretical interest in unlimited variety, as is evidenced by our requirement of uniqueness in the individual thing. Again, much of the basic uniformity of various areas of experience is not discovered but imposed by categorical procedures which argue nothing intrinsically orderly in what is given. Outstanding examples are the serial and dimensional orderings of qualitative variety, as well as schematic classifications, on the basis of similarity, by which an indefinitely large range of possible variety is brought within a definitely limited number of alternatives.

If now, I may suppose that this inadequate examination will be sufficient to guard against the commoner misapprehensions about the "uniformity of nature," I should like to proceed to those considerations which I believe to be really central for our problem. What is required in the way of order if experience is to be intelligible and knowledge possible is only that there should be apprehensible things and objective facts – and to this we can conceive no alternative whatever, unless it be the non-existence of everything.

As should now be evident, the existence of an apprehensible thing is not assured by the mere givenness of experience, though if there were no things for us, there would be, in an obvious sense, no experience. Things exist for our apprehension as certain sequences of possible experience, of which given presentations are probable indices. For this, the sole necessity is that, certain presentations being given, the possibilities of further experience should not be unlimited; that is, that it should not be the case that every recognizable appearance is equally associated with, or followed by, every other. Let us give this fundamental requirement of knowledge formal statement: *Principle A*; It must be false, that every identifiable entity in experience is equally associated with every other. This principle is what Mr. Keynes has called the "limitation of independent variety,"[3] except that it is here applied to the identifiable constituents in experience, particularly with reference to their sequence, instead of to the qualities of objects with reference to their correlation in reality.

What I wish to point out is, first, that this single requirement satisfies everything which is necessary, in the way of order in experience or reality, for the validity of empirical generalizations, based on past experience and applicable to the future; and second, that although this has the appearance of a limitation of the possibilities of experience it has in the end no alternative. To put it in paradox; every possible experience is *ipso facto* a possibility of experience, but it is not possible that all possibilities should be actual. Any possibility is a possible actuality, but it is not possible that all possibilities

[3] *A Treatise on Probability*. Ch. XXII.

should be concomitantly real. The coincident actuality of all possibilities is impossible. Thus the requirement that actuality be a limitation of the all-possible, is not itself a limitation of the possibilities. Instead, it is something which could not conceivably fail to be the case; there is no alternative.

Let us turn first to the requirement that there should be apprehensible things and objective facts. As has been pointed out, the existence of things and the possibility of our knowing them – in the only sense in which we *can* know them – does not require that what we attempt to regard as things should be in each and every case objective realities. Given appearance is no more than a probable index of the existence of such a particular reality. Furthermore, any particular substantive concept, even though it should be current for a thousand years, may eventually turn out to represent, not an objective thing, but a mistaken reification. The concatenation in experience which the applicability of the concept requires may not, in fact, obtain. There may be no unicorns; there may be no disease entities; there may be no such thing as the soul. If the reality of knowledge required that every uniformity which we seek, by the invention of a concept to designate it, should be present in possible experience, or if it required that every given appearance should be an index to some uniformity which could be predicated with certainty, then it would not be plausible that there is any such thing as knowledge. All that is required is that given appearances should be probable indices to such uniformities as may be designated by concepts. This in turn means that statistical generalizations from the past sequences of experience must establish in some measure their probability for the future. And this, again, depends, as has been stated, upon the limitation of independent variety in the correlation between given appearances and further possibilities of experience.

The point may be made clear by an analogy which, as the reader should be warned, is incomplete but may nevertheless be useful. Suppose that we observe a certain sequence in cards, dealt from a pack, to be repeated several times. Will this establish a probability of its future repetition? If we may suppose some limitation of the possibilities, such as adhering of the cards or trickery in the deal, it may. But if we suppose no such limitation upon those ideal conditions which packs of cards and their shuffling are meant to approximate, then even numerous repetitions of an observed run will not in the least increase the antecedent probability of its future occurrence. If, then, we may compare identifiable qualia and complexes of such (recognizable appearances) to the cards, and experience in general to an ideal pack under ideal conditions, a statistical generalization of past sequences in experience could not establish that in future one such sequence should be probable as against others in which the given appearance should be the same. That is, no appearance would be probable index to further possible experience. Since what any substantive concept denotes in experience is some definite sequence or set of such, there could be, in an experience which was subject to no limitation upon the all-

possible sequence of given presentations, no recognition of things by their appearances as even probable.

But – to continue our analogy – if we can suppose the pack from which cards are dealt to be defective or the dealing subject to trickery, then a statistical generalization as to past runs will establish a genuine probability for the future, and the continued verification of such a generalization will continually increase its probability. It will still be the case that any *particular* generalization of this sort may represent "mere coincidence" in the past and fail in future. But the point which it is especially important to observe is that if the assumption that there *are* limitations which some uniformity of sequence *might* reflect is a warranted assumption, then this fact of itself is sufficient to establish the validity of the argument, in any particular case, from past uniformity to its probability for the future. If, however, it should be positively known that the runs of cards are ideally governed and subject to *no* such limitation, then there would be *no* such probability. The especial point here is that the validity of arguing from any past coincidence to its probability in the future does not depend upon our knowing any *particular* ground for this *particular* uniformity (other than its past occurrence), but does depend upon our knowing – as at least possible – a ground for such uniformities *in general*.

So far the point of our analogy is, that the validity of arguing from the correlation between a given presentation and that further experience which means a particular kind of object denoted by a particular concept, does not require us to know any particular reason for that particular correlation or for the existence of just that sort of thing (other than the past experience itself). It requires us to know – as possible at least – that such correlations, things *in general*, exist. If this assumption is valid, then the prediction (as probable) of that future experience which means the verification of the presence of an object corresponding to a particular concept, from a given presentation with which such further experience has been associated in the past, is valid; and the probability is equally genuine when, as a fact, the past conjunction is a "mere coincidence" which future experience will prove not to be valid as a generalization. That is, mistaken apprehensions, as *probable judgments*, will, if there has been no logical error in the judgment, be valid, as much as those which are actually verified by the future.

It is also to be noted that, if the assumption that things in general exist should be valid, then the probability for the future of the correlation between a given presentation and certain further experience will be increased with each successive verification of that correlation. The particular principles of probability upon which this rests need not be examined here;[4] the reader will perhaps be satisfied upon the point by consideration of the analogy: if we have ground for assuming poor shuffling or interference or some such limitation,

[4] Of this point, see Keynes, *A Treatise on Probability*. Ch. XX.

the probability for the future of a particular run which has been repeated will increase with each repetition of it. At least this will be so after a certain number of repetitions have already occurred, if we suppose the conditions unaltered.

This assumption of the existence of things, that is, of certain recurrent correlations in the sequence of possible experience, is all that is required for the validity, as probable, of empirical generalizations or "laws," and of the argument from past to future with respect to these. It will be evident from previous chapters that the existence of objective properties is conditional upon precisely this same type of uniform sequence in experience. The verification of such properties requires precisely the same connection between given appearances and further possible experience, and requires nothing more. Obviously the assumption of objective properties is involved in the assumption of things. Furthermore, if things exist, which are cognizable and therefore the objects of possible concepts, it is evident that there must be laws. Laws prescribe, or describe, precisely such uniform sequences. In fact, although laws or empirical generalizations formulate relations of objects, or properties of objects, which are non-essential rather than essential, this difference is irrelevant to the possibility of knowledge. What is essential in a thing is determined by the particular concept which it serves our interest to apply, rather than by anything else. The properties essential to "a stone" do not include its being "a freely-falling body," and the essential properties of a "freely-falling body" do not include its being a stone. But certain laws or generalizations must hold of an object in order that it be a stone and certain others must hold in order that it be a freely-falling body. The laws which characterize or constitute essential properties of freely-falling bodies are non-essential or merely empirical generalizations about stones under certain circumstances. Moreover, not only are all essential properties capable of representation as laws, but every empirical generalization is such that some substantive concept is capable of being framed so as to require conformity to it as the distinguishing or essential property of a particular kind of thing. Scientific concepts especially have this character explicitly; they define or classify objects on the basis of their conformity to certain laws, prescribing modes of behavior. Indeed, any objective fact – meaning by this any state of affairs which is describable in conceptual terms – is a property of objects and may be denoted by a substantive concept marking it as essential. In fact, unless the whole point of the last two chapters has been lost, it will be clear that the difference between essential and non-essential properties, and between prescriptive laws and empirical generalizations, is one determined by pragmatic considerations of the particular interests our knowledge is to serve which dictate particular modes of analysis, rather than by any difference in the objective state of affairs upon which these are directed. *What* laws *must be* valid, would depend upon what things exist; but the general assumption

that there are things (of some sort) includes the assumption that there are valid generalizations of the type of law. If there could not be a world without the uniformities of possible experience requisite to the existence of things, then there could not be a world without uniformities of the type of law.

As is the case with things, so too with law, the validity of the prediction that a particular generalization which has held in the past will likewise hold in future, depends upon the general assumption that *there are* laws. If there are such uniform sequences as laws describe, then the occurrence of one such in the past establishes a probability of it in future, and each successive verification increases that probability. And here, too, the probability-judgment, if logically drawn, will be valid even in those particular cases in which future experience will prove past instances to have been "mere coincidences" and the generalization to be false.

Thus the assumption that things exist – that there are (some) such recurrent sequences as substantive concepts require for their application – is sufficient to secure the validity of knowledge in general, when the nature of empirical knowledge is correctly interpreted as probable judgment. As has been remarked previously, the form which skepticism has often taken, of doubting the validity of all empirical generalizations while leaving unquestioned the existence of apprehensible things, in terms of which such dubious generalizations could at least be intelligibly phrased, represents a totally impossible position. It could only *seem* self-consistent on the assumption that the validity of knowledge requires the *certainty* of empirical generalization and of prediction. Since any reasonable examination of knowledge must conclude that the pretense to such certainty is unwarranted and the ascription of it is a misreading of the actual nature of science and of common-sense attitudes, what such skepticism has slain is a man of straw, though to be sure it is just this scarecrow which has frightened philosophers out of their wits for a considerable period.

Before passing on, we should remind ourselves once more at this point that the assumption of the existence of apprehensible things does not mean the assumption that experience is uniform in the sense that certain determined sequences *universally* follow upon a given first term (the presentation). If it meant that, then no apprehension of a thing would be valid unless the given presentation should be such as to render mistaken apprehension absolutely impossible. Since errors of apprehension are possible and identification of objects are probable, it follows that the prescribed sequences, requisite to the existence of things, are such as would be predictable, with certainty, only in terms of some larger whole of experience than can be included in a single presentation. Our actual predictions – our actual knowledge of things, predicated upon given presentations – is in terms of such sequences of experience as admit of exceptions such as mistake and illusion. Hence as generalizations about actual experience, the existence of apprehensible things means only such

uniformity as can be formulated in generalizations of the statistical type, which admit of exception. *No absolute uniformities* of actual experience are required either for the existence of things or for the objective character of law. Laws too, of course, are exempt from being proved false by mistaken apprehensions of the things or objective facts with which we suppose ourselves to be dealing.

The examination of the categories, "thing," "event," "property," "relation," "law," is a most difficult and complex matter. I make no pretense to have exhausted even the essential considerations for any one of these. In particular, I should not like to seem to assert that there is no difference between what is requisite to the nature of a thing and to the objectivity of law. The attempt is only to show that there could not be a world of apprehensible things in which empirical generalizations should fail of valid foundation; that if there are things then laws of the type which empirical generalization seeks to grasp must hold; and hence that such generalizations may be genuinely probable and that empirical knowledge, as the only sort of thing it can reasonably be supposed to be, is genuinely possible.

If this point is established, then the only alternative to the conception that our knowledge in general is valid, is the conception that there are no things; that nothing exists to be known and no mind exists to know it. The nearest approximation we can make to such a conception is, perhaps, that there might be an experience which is a mere flitting of meaningless presentations. But for such experience, if we can conceive it, the distinction of "real" and "unreal" could have no meaning. This being so, it is a little obscure just what we suppose ourselves to be talking about when we try to frame such a conception; perhaps about the experience of an oyster with the oyster left out.

I do not mean to take advantage of the fact that skepticism can only make itself intelligible in terms which render it not self-consistent. This is a fact, and a most important one. But it might be claimed – though I do not know that it ever has been – that skepticism intends only to exhibit a *reductio ad absurdum* of the pretense to knowledge, by beginning with definite assumptions about the mind, etc., and on that basis proving the invalidity of these assumptions along with every other.

This possible intent of skepticism seems the more important to examine because it would appear, in the above, that the account of knowledge here given avoids skepticism only by an assumption which has a conceivable alternative; and that this alternative is precisely the absence from experience of all order of the kind which means significance and intelligibility. In this situation, it might be said: "It is not humanly possible to divest ourselves of assumptions – such as the existence of definitely conceivable things – which have no rational foundation, and still talk or think, but it is possible to be sufficiently self-critical to realize that such unavoidable assumptions are nonrational and mere 'animal faith'."

I believe this to be demonstrably false, and shall attempt to make this fact clear. But before approaching that topic, there are two points about skepticism with the above meaning, which it may be well to observe.

Historically there have been two main grounds of skeptical conceptions, the relativity of sense-perception and the absence of "necessary connections" in experience. Quite often these are confused together and results appropriate only to the first are added to the second. It is the first of these only which gives plausibility to the conception that there is a reality which is unknowable to us because we are separated from it by the manner of our apprehension. This ground of skepticism has, I hope, been dispelled by the considerations of previous chapters. It neglects the fact that "real" is systematically ambiguous; that "appearances" themselves must constitute one kind of reality. It also neglects the further facts that reality of any sort is definable and meaningful only in terms of *some* experience, actual or hypothetical, and that regardless of the relativity of perception, appearances inevitably are, for a rational understanding, a ground of *true* knowledge of the reality which appears even though that knowledge should be incomplete. As a result, it is impossible to conceive "reality" as completely unknowable; and since it is not plausible that, under actual or realizable conditions, reality can be *completely* known to us, the significance of the "unknowable" dwindles to the commonplace fact that humans are not omniscient. Nothing in the train of thought which starts from the relativity of perception can in any way vitiate such knowledge as we *have* or seem to have. The ground of this sort of skepticism is the false conception of knowledge as representation.

The other type of skepticism turns upon a correct conception of knowledge as predictive judgment. Its particular ground is the absence of "necessary connections of matters of fact." This may well be equivalent to the falsity of the assumption which has here been shown requisite to the existence of apprehensible things. Actually, of course, Hume supposed that necessary connections must mean such iron-clad uniformities in experience as would enable certainty of prediction, whereas it is only genuine probability which is requisite. But I hope it will be clear that if this is the ground of skepticism, it is quite unwarranted to supplement this conception by a notion of a reality somehow concealed from us by the chaotic character of experience. The *logical* conclusion would be that of Gorgias, "Nothing is," or at least the admission that we can have no rational ground for asserting a reality of any sort. If we cannot humanly avoid this, that is merely to observe the fundamentally irrational character of our "animal faith" and the *reductio ad absurdum* of all attempts at consistent belief.

The second point to be observed before we pass on, is that we must not confuse such irrational "animal faith" with that wholly rational attitude of him who, acting on the basis of a *probable* judgment, confronts the future he predicts with the realization that the possibility of his being disappointed is

a real one. In both cases, one would face the future with an attitude determined by past experience but one which, in the particular instance, the future might prove to be fruitless. But in the one case, this attitude has no rational ground and incorporates no truth; in the other, it represents knowledge – of probability – which is not only rational but absolutely true, whatever the dénouement. If one should ask, "But what, practically, would be the difference?" that is a point which we shall reach shortly.

We come now to the main point: it is impossible to imagine any sort of experience which would not present such statistical stabilities as would validate probable prediction, and such as would represent the experience of things. Our analogy of experience to runs of cards is, on this point, as unfavorable as could easily be devised, because packs of cards and their manipulation are intelligently directed to the end of minimizing the possibilities of prediction in those respects which determine the outcome of the game. But it is worth remarking at the outset that the point of card-games, except for children, is to pit our wits against this maximal uncertainty and determine a long-run outcome favorable to ourselves in spite of it. If the sequence in experience should be as independent and lacking in "necessary connection" as the sequence of cards, that could not frustrate prediction or destroy the practical value of probability-judgments. Indeed if cards should represent, in the analogy, recognizable qualia or complexes of such in presentations, our attention should be drawn to the fact that, on this point, the analogy is better than might be supposed. There are no sequences in experience which are determinable with certainty by a given presentation alone. Real things represent stabilities of a type which enormously transcend what can be given in any one experience. If the reality of things required the presence in experience of sequences absolutely determined by a first term, then we should have no reason to believe in their existence. As has been pointed out too often already, what is required is only that a given presentation determine a probability of future possible experience.

The reason why Principle A imposes no actual limitation upon the possibilities of experience may be formulated in a second dictum: *Principle B*; In any situation (if sufficiently extended) in which there are identifiable entities which fail to satisfy Principle A – *i.e.*, whose association is "random" – there will be other entities, systematically connected with the former or specifiable in terms of them, which do satisfy Principle A. The principal methods by which we determine "orderly" constituents of experience in terms of "random" ones are by proceeding to simpler elements through analysis, by taking a larger whole into which the primary constituents may be organized, or by confining attention to *abstracted* elements, and disregarding the remainder of the given as irrelevant.

To revert to our analogy, if the sequences of cards are purely random or subject to no laws but those of chance, then the stable entities of card-games,

comparable to things, will be something such as tricks-taken, or suits, or kinds of hands such as full-houses, straights, etc. Or they will be entities of a lower order such as the pips on the cards. As is obvious, the chance character in the sequence of dealt cards does not frustrate the attempt at statistical generalizations which give guidance for successful play. Even with entities thus deliberately devised to approximate pure chance in certain ways, there are certain wholes which, neglecting the "non-essential," give rise to generalizations. In fact, no better basis for statistical generalization could be devised than the known fact that certain constituents of the situation are distributed in genuinely "random" fashion. Since any departure from "pure chance" is itself subject to generalization of some sort, a statistical basis for probable judgment cannot conceivably fail to be afforded.[5]

What particular stabilities, and what types, are to be found, cannot be prescribed to experience or reality. The *particular* order discoverable in reality, the extent of it, and the degree of its conceptual simplicity, are of course, absolute data. The supposition that we may always find law in terms of any experimental entities we please and with predetermination of the type of the uniformity to be found, is totally unwarranted and is unnecessary to the validity of knowledge. Our concepts are devised with purpose to catch the significant, the subject of meaningful generalization, at whatever level and in whatever way we may. When particular concepts fail, we merely abandon them – through analysis or organization or abstraction, and so on – in favor of corrected ones, which take cognizance of, and include the ground of, our previous failure. That conception *in general* should be invalid, is quite impossible. The attempt to envisage an experience or state of affairs such that *every* attempt to discover stabilities must fail, is the attempt to conceive the inconceivable – to conceive what would not be things or objective facts nor subject to any generalization which makes what is denoted conformable to concepts. The experience or reality which should be incompatible with conception, *ipso facto* cannot be conceived.

It may seem that there is one aspect of the matter not yet covered; the validity of the argument from past to future. It may appear that it would be possible, not only that *particular* predictions based upon the past should be useless as anticipation of the future – which their character as probable allows – but that *in general* the anticipation of the future in the light of the past is without theoretical warrant. This point really is covered by Principle A, when we remember that the kind of association of constituents in experience which is essential to their comprehension in things is sequence in possible experience. But when we remember that it is the validity of *probable*

[5] In this connection, the analogy will be improved if we think of our predictions about runs of cards as based on past runs (as they might be), not upon prior knowledge of the constitution of the pack.

prediction only which is required, the matter can be more explicitly stated, and quite simply: *Principle C*; the statistical prediction of the future from the past cannot be generally invalid, because whatever is future to any given past, is in turn past for some future. That is, whoever continually revises his judgment of the probability of a statistical generalization by its successively observed verifications and failures, cannot fail to make more successful predictions than if he should disregard the past in his anticipations of the future. This might be called the "Principle of statistical accumulation." It is quite evident that it holds even with respect to what is determined only by "pure chance" – in the only sense that we can conceive anything such. This is what is meant by saying that probability or chance is measured by that fraction which is approximated "in the long run."

Though the attempt to envisage what would frustrate conception and knowledge is, in the nature of the case, futile, it may be worth while to conceive the worst possible experience, from that point of view, by a somewhat fantastic illustration. Let us think of our experience as constituted by complexes or patterns of qualia which come to us in sequence, and let us suppose that this experience is given to us, not by a Berkeleian God who in his goodness preserves certain uniform sequences in order that we may predict experience according to natural law, but by a perverse demon whose sole purpose is to mislead us and render knowledge impossible. If the distinguishable sensory qualia should be finite in number, as they are in actual experience, this demon must necessarily repeat, but he might repeat identifiable complexes and previous sequences to as small a degree as possible. However, if, as a result, these presented patterns did not afford a sufficiently good basis for conception, we should analyze them into sub-patterns or other constituents which would be of more frequent appearance, or should classify them according to some simplified schematics based on similarity, or give them dimensional or serial arrangement approximating to an ideal continuum, or in some other fashion proceed by abstraction or reorganization or a combination of the two to circumvent the multifarious variety of the given. For the rest, the character of it would be relegated to the "non-essential" and merely mark the relative uniqueness of particular moments of experience; it would be non-significant, like the particular character of frost-patterns and snow crystals. We should be inattentive to such non-significant features of the given; and if any one should call our attention to their comparative frequency, we might regard his observation as a foolish remark about the obvious but unimportant. If the demon should likewise minimize the extent to which particular *sequences* should be repeated, he might make knowledge difficult to a degree. But at least we should presumably come to possess the very important generalization that the maximum of novelty may confidently be expected. We should organize all our conduct on the principle that "lightning seldom strikes twice in the same place" and "history never

repeats," with consequent advantage to ourselves. As a fact, however, we should circumvent the demon on this point at the same time that we attained relative simplicity of recognition, and should carry out similar procedures with reference to sequence. We should analyze, abstract, and relegate what we could not find somehow significant to the status of "irrelevant concomitants of significant 'causal' sequences." By ignoring a sufficient proportion of the characteristics of experience as it came to us, we should arrive at such simplicity that, in terms of it, even the most disadvantageous sequence of the primary constituents – *e.g.*, a "random" order – must afford some repetition and uniformity. Knowledge might be made difficult, but could not be made impossible.

This would be something as if we were required to play a game with cards dealt from a pack we never saw and could only infer from the hands dealt us, and as if these cards were dealt with trickery and malice – something worse than a good decent game of chance. But even in such circumstances, the principle of statistical accumulation would operate. If we were required to bet on this game, we might be unequal to our demon antagonist to any degree you please; our ignorance might be great, and our failures and loss correspondingly large. But by nothing which he could do could be so devise it that we should not lose *less* of our money if we intelligently observed past dealings and continually revised our betting on the basis of accumulated experience.

Indeed we need only to prod our imaginations to remark that this actual experience of ours fits the illustration better than one might suppose. Most of the pattern and sequence of our experience is non-significant; those characters which by our practical attitude we single out and remark and make prediction in terms of, are inordinately meager as compared with the total of presented distinguishable pattern and sequence of qualia. Most of experience is as non-significant as the intricate pattern of the rug I have been gazing at is to me now. Beyond a few details which suffice for recognition, this intricacy does not even draw attention, and if attended, it hardly functions as knowledge. It neither verifies anything nor baffles knowledge, because it arouses no anticipatory attitude. Confronting any given experience, the first act of intelligent cognition is to discard all but a few items of what is presented as excess mental baggage irrelevant from the point of view of our predictive purpose. It is the relatively meager remainder which constitutes the clue to expected uniformity.

Even if the hypothetical demon should have an infinite number of qualia and complexities at his disposal, instead of a finite number, it is doubtful if we should be worse off. We should merely discard more of our experience, as marking that uniqueness of each moment and each thing which is irrelevant to knowledge; we should frame our concepts and make our predictions in terms of the remainder, or of abstractions and other such imposed simplifications. On any hypothesis which can be framed about experience, however

perverse, I think it will be clear that a similar thing would hold, or else that the fantasy is not even imaginable but would merely mean the elimination of reality, of significance, of all questions and the mind itself.

In any experience such as we can, even at the worst, suppose our own to be, conception will be valid and knowledge will be possible. The three principles which have been stated will hold, and generalization will be subject to genuine probability. No further and avoidable metaphysical assumption is required. The mind will always be capable of discovering that order which is requisite to knowledge, because a mind such as ours, set down in any chaos that can be conjured up, would proceed to elicit significance by abstraction, analysis and organization to introduce order by conceptual classification and categorical delimitation of the real, and would, through learning from accumulated experience, anticipate the future in ways which increasingly satisfy its practical intent.

PRAGMATISM AND CURRENT THOUGHT

C. I. Lewis. "Pragmatism and Current Thought." *Journal of Philosophy* 27.10 (24 April 1930): 238–246.

It is somewhat difficult in the case of pragmatism to determine what are its essential and distinctive theses. That there should be thirteen distinguishable pragmatisms, however, is not a peculiarity: these could be set alongside the thirty-seven idealisms and fifty-one realisms. William James is reported to have said that be was pleased to find that pragmatism had this wealth of meaning; he accepted all thirteen. In any case, such variety merely marks the fact that pragmatism is a movement, not a system. Its beginnings are attributable to Charles Peirce. But Peirce has something the quality of a legendary figure in American philosophy. His originality and the wealth of his thinking are not fully evident in his published writings. Apart from a few persons – amongst whom were James and Royce – some of his most important conceptions can have had little influence, because they have never been printed: and the coincidence of these doctrines with the views of later pragmatists is distinctly limited. James's enthusiasm for them must in part be set down to that catholicity of appreciation which was so notable a part of his character; James called himself a "radical empiricist" as well as a pragmatist, and the connection, or lack of it, between these two aspects of, or strands in, his philosophy, has been a matter of some question. We must, of course, look to Professor Dewey's writings for the integration and systematic elaboration of pragmatism. But no one could have exercised the quite unparalleled influence which he has had upon American thought without giving rise to a wealth of resultant views which is a little confusing when one tries to grasp then coincidence or central meaning. Hence it is not a matter for surprise if those most deeply influenced by him show a tendency to drop the term, lest a too extended agreement with one another be suggested, and that those of us who still have ventured to use it are doubtful of our right to the designation.

If, then, I venture to suggest what is the core of pragmatism, and what I think may be the chief significance of it, both in philosophy and for other branches, I hope it will be understood that I do not take myself too seriously in the matter. This view is presented to those who will best know how to correct my mistakes.

Pragmatism is, as James indicated, not a doctrine but a method: viewed logically, it can be regarded as the consequence of a single principle of

procedure. But this principle, though by itself it says nothing material in the field of metaphysics or epistemology, and though its application is by no means confined to philosophy, has nevertheless a wealth of philosophic consequences. It implies at least the outline of a theory of knowledge; and if it dictates no metaphysical theses, at least it rules out a good deal which has been put forward under that caption, and it operates as a principle of orientation in the search for positive conclusions.

I refer, of course, to the pragmatic test of significance. James stated it as follows: "What difference would it practically make to anyone if this notion rather than that notion were true? If no practical difference whatever can be traced, then the alternatives mean practically the same thing, and all dispute is idle."[1] Peirce formulated it with respect to substantive concepts rather than propositional notions – though the two come to the same thing: "Our idea of anything is our idea of its sensible effects.... Consider what effects that might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object."[2] It is one importance of this pragmatic test that it is so obviously valid and final: once it has been formulated, there can be no going back on it later without conscious obscurantism. Any consequence of it, therefore, shares in this imperative and binding character. Peirce's dictum draws our attention to the fact that there is a kind of empiricism which is implicit in the pragmatic test: What can you point to in experience which would indicate whether this concept of yours is applicable or inapplicable in a given instance? What practically would be the test whether your conception is correct? If there are no such empirical items which would be decisive, then your concept is *not* a concept, but a verbalism.

If one does not find in Professor Dewey's writings any terse formulation which is exactly parallel (and of that I am not sure), this is only because here the pragmatic test is clothed with its consequences; it pervades the whole, and is writ large in the functional theory of the concept. Ideas are plans of action; concepts are prescriptions of certain operations whose empirical consequences determine their significance. This connotation of action is not, of course, a new note; it appears in Peirce's emphasis upon conduct and experiment, and in James's doctrine of the "leading" character of ideas. Is this functional theory of the concept implicit, like empiricism, in the pragmatic test?

[1] *Pragmatism*, p. 45.

[2] "How to Make Our Ideas Clear," *Chance, Love and Logic*, p. 45. Compare: "... Since obviously nothing that might not result from experiment can have any bearing on conduct, if one can define accurately all the conceivable experimental phenomena which the affirmation or denial of a concept could imply, one will have therein a complete definition of the concept, and *there is nothing more in it*. For this doctrine he [the writer, Peirce] invented the name pragmatism." – "What Pragmatism Is," *Monist*, Vol. 15, p. 177.

So far as Professor Dewey himself is concerned, it would appear that this doctrine antedates his explicit pragmatism, and may have been the root of it. (Perhaps he will tell us.) It appears in his paper on "The Reflex Arc Concept in Psychology," the first important document for "functional psychology," published in 1896.[3] He there criticizes current psychological theory as not having sufficiently avoided the fictitious abstractions of sensationalism. "The sensation or conscious stimulus is not a thing or existence by itself; it is a phase of coördination."[4] "A coördination is an organization of means with reference to a comprehensive end."[5] "The stimulus is that phase of the forming coördination which represents the conditions which have to be met in bringing it to a successful issue; the response is that phase of one and the same forming coördination which gives the key to meeting these conditions, which serves as instrument in effecting the successful coördination.... The stimulus is something to be discovered.... It is the motor response which assists in discovering and constituting the stimulus."[6] Substitute "sensation" or "sense data" for "stimulus," "operation" or "action" for "motor response," and what is here quoted will be found occupying a central place in all Professor Dewey 's subsequent expositions of his pragmatic doctrine. Three years later, he wrote: "I conceive that states of consciousness ... have no existence as such before the psychologist gets to work." "Knowing, willing, feeling, name states of consciousness not in themselves, but in terms of results reached, the sorts of value that are brought into experience."[7]

If, then, I am right in the derivation here assigned, Professor Dewey's functional theory of knowledge is the necessary consequence of a methodological principle applied to psychology; namely, that concepts used should designate something concretely identifiable in experience, not abstractions apart from that which serves for their empirical discovery. Sensations, or sense data, are condemned as not thus identifiable apart from the responses to which they lead and the ends such action serves.

The functional theory of the concept has, as I have tried to show elsewhere, other grounds, of a more purely logical sort. Viewed in this way, however, and apart from psychological considerations, it is not, I think, a simple conse-

[3] *Psychological Review*, Vol. 3, pp. 357–370. My attention was drawn to this by its citation in Boring's *History of Experimental Psychology*, pp. 540–541.

[7] "Psychology and Philosophic Method," address before the Philosophical Union of the University of California, 1899, pp. 6 and 10. It is interesting to remember that in the preceding year, James presented the first statement of *his* pragmatism, "Philosophical Conceptions and Practical Results," under the same auspices.

quence of the pragmatic test, but has a conceivable alternative, namely, immediatism or the presentation-theory of knowledge. By this logical approach, one has to adduce reasons for repudiating the conception that empirical knowledge – or *some* empirical knowledge – is immediately given, in order to reach the conception that activity and its issue are indispensable and characterizing factors in empirical cognition. The theory that meanings connote action and truth connotes prediction, is implicit in the notion that truth and meanings are something *to be tested*; hence, that they do *not* bring their own warrant in being simply given.

I believe we here arrive at a turning-point in pragmatic theory.[8] On the one side, the pragmatic principle seems to stress the directly empirical. Put enough emphasis on that and one might conceivably – though not validly, I think – arrive at a highly subjectivist theory, of knowledge as immediate. On the other side, it stresses the limitation of meaning to what makes a verifiable difference, and of truth to what can be objectively tested. Follow out the consequences of *that*, and of the functional theory of knowledge which it implies, and I believe one is inevitably led to the doctrine that concepts are abstractions, in which the immediate is precisely that element which must be left out. To this point, I should like to adduce certain illustrations, drawn from contemporary science.

The new physics is, in good part, based upon certain applications of the pragmatic test. And to these physicists the validity of this methodological principle and the functional interpretation of conceptual meanings seem to be simply synonymous. One main premise of physical relativity is, of course, the impossibility of deciding which, of two bodies in relative motion, is at rest with respect to an absolute space. (We may remind ourselves that James's illustration of the pragmatic test – the man and the squirrel – is simply an example of the relativity of motion to frames of reference.) In elaborating the consequences of this relativity of motion, it became necessary to repudiate other absolutes, such as length, time, simultaneity, etc.; and this was done by identifying these with the actual modes by which they can be tested – the pragmatic test once more. The resultant methodology may be generalized in what Bridgman calls "the operational character of concepts." "We evidently know what we mean by a length if we can tell what the length of any and every object is, and for the physicist nothing more is required. To find the length of an object we have to perform certain physical operations. The concept of length is therefore fixed when the operations by which length is measured are fixed: that is, the concept of length involves as much as and

[8] When this was written, Professor Burtt's paper, "Two Basic Issues in the Problem of Meaning and of Truth," contributed to *Essays in Honor of John Dewey*, had not yet come to hand. I note with pleasure that a part of his paper and part of what is here written run parallel.

nothing more than the set of operations by which length is determined. In general we mean by any concept nothing more than a set of operations; *the concept is synonymous with the corresponding set of operations.*"[9]

Why does the physicist thus identify his concepts with operations of testing? Is it because the properties he is concerned with are peculiarly those which are difficult or impossible of immediate apprehension? Not at all. Suppose a critic to observe: "But of course your concept of length goes back to an immediately given somewhat. You test the relation of a particular length to the yardstick, but unless your yardsticks were an immediate so-longness, directly apprehended, your concept of length would be entirely empty." He will reply that this immediate so-longness has nothing to do with physics, because it can not be tested. The *yardstick* can be tested; as it happens, the measurement of it will differ for different relative motions. But any immediate so-longness of it is something which makes no difference to physics: if it had one so-longness to *A* and another for *B*, that would be unverifiable and ineffable. It is the significance of the operational character of concepts to extrude such ineffables from physics. Subjectively it may be that *A* and *B* both seem to themselves at rest in the center of the universe, directly apprehending certain so-longnesses, so-heavinesses, felt endurances of things, and what not. But physical position and motion are simply relations to a frame of reference, physical time a relation to clocks; physical properties in general consist in those operations and relations by which they are assigned and tested. The standards are absolutely standards – that is, arbitrary – but they are not absolute in any other sense. The standard yardstick, or clock, or whatever, has its length or the measure of its seconds, etc., in an entirely similar and verifiable set of relations to other things, and only so. Any immediate content of the concept is extruded by the principle of the pragmatic test. If your hours, as felt, are twice as long as mine, your pounds twice as heavy, that makes no difference, which can be tested, in our assignment of physical properties to things. If it *should* thus make a difference in our predication of properties, we should at once decide that one of us must be mistaken. Such decision would reveal our implicit recognition that our concept of the predicated property excludes this subjective element, and includes only the objectively verifiable relations.

The physical concepts are not, by this extrusion of the immediate, emptied of meaning. Their meaning is, as Bridgman says, in the operations of verification and their results; it is contained in that complex network of relationships which constitute the laws and equations and physical predications of which the science consists. The concept is, thus, merely a sort of configuration or relational pattern. Whatever the immediate and ineffable content which is

[9] *The Logic of Modern Physics*, p. 5; italics are in the text.

caught in that net may be – for John Jones or Mary Doe or anybody – it does not enter into the science of physics. The resultant conception of the content of the science is admirably expressed by Eddington: "We take as building material *relations* and *relata*. The relations unite the relata; the relata are the meeting points of the relations."[10] The conceptual in knowledge is the element of pure structure or operational construction.

Thus the pragmatic test becomes a kind of law of intellectual parsimony, and leads, in science, to what might be called "the flight from the subjective." Physics is by no means an isolated example: the parallel thing has happened, or will happen, in every science, because it is simply the extrusion of what the science can not finally and conclusively test. Mathematics, being the oldest science, did it first. Geometry begins with rope-stretching and ends as the deductive elaboration of purely abstract concepts, the problem of the nature of space being handed over to physics and philosophy. Arithmetic begins with counting empirical things and ends in the logical structure of *Principia Mathematica*, for which the existence of the number 8 (for a certain type) requires an extraneous assumption. Just now mathematics threatens to go further and restrict itself to systems of operations upon marks. Psychology first got rid of the ineffable soul; a pragmatic psychologist then asked, "Does consciousness [as distinct from its content] exist?" and now we have behaviorism, based on the methodological principle of restriction to what is objectively verifiable. If some of these movements go beyond what is necessary or valid, at least they exhibit the tendency, and the ground of it.

Professor Dewey seems to view such abstractionism in science as a sort of defect – sometimes necessary but always regrettable; an inadequacy of it to the fullness of experience. In various ways, it seems to him to threaten the relations between knowledge and life. Professor Eddington's book suggests that a doubt on this point besets him too when, as physical scientist, he finds himself also constrained to assess philosophical significances. That the world as experienced and life as lived are not going to be thrown out of the window goes without saying. Particularly for Professor Dewey, it seems to me that this apprehensiveness is misplaced, because he has himself indicated the main considerations essential for the solution of the problem which results – the problem of the relation of abstract concepts to the concrete and directly empirical. Time does not permit attention to all the pertinent considerations. But I wish to suggest one which is important, by a final illustration, drawn once more from physics.

As an eventual result of subatomic and quantum phenomena, the new physics has abolished imaginable matter. Analysis of the physical emerges finally in something like Schrödinger's ?-functions, in mathematical expressions of probability, concrete representation of which can only be approached

[10] *The Nature of the Physical World*, p. 230.

in terms of an admittedly fictitious sub-ether of variable dimensions. Immediately apprehensible matter dissolves into mathematics. Two other expressions of this same abstractness of the physically ultimate occur in Eddington's later chapters: one is that statement about relations and relata, already referred to; the other is to the effect that physics reduces the concrete object to pointer-readings.[11] The elephant sliding down the grass slope is at once an immense flock of ?-functions getting integrated, and a set of pointer-readings. The two interpretations do not seem interchangeable. Let us fasten on the pointer-readings. Why reduce the elephant to pointer-readings? In the first place, because physics can not deal with the elephant as a whole. It comprehends a good many – perhaps most – of the elephant's properties, but that he is, for example, a wonderful fine fellow and very intelligent, must be omitted from physical consideration. Let us call that organization of properties which physics *can* deal with "the physicist's elephant." Why is the physicist's elephant reduced to pointer-readings? First because, with the apparatus oriented upon the elephant, the elephant *determines* the pointer-readings. Second, because such pointer-readings are a conveniently hybrid sort of reality: the apparatus and pointers being physical, their readings correlate with the properties of the elephant; and the readings being numerical, they translate those properties into mathematical values. The significance of the pointer-readings is merely for the purpose of such translation. The last state of the physicist's elephant, like the last state of the electron, is in mathematical functions. But this last stage for the *physicist* is merely an intermediate stage of operations with respect to the elephant. The numerical values given by the pointer-readings are substituted for the variables in some mathematical equation expressing physical law. They thus determine a numerical value of some other mathematical function. This last can be translated back into something of the order of pointer-readings, and hence back into some other and previously undetermined property of the elephant – with the eventual result, perhaps, that we get the elephant safely into a box-car. Such eventual result is the reason for being of the whole set of operations. If it be asked, then, "Why reduce the elephant to mathematical functions?" the answer is that this is the best way known to man for getting him into the box-car.

The physicist's elephant is an abstraction, but a rather palpable sort of abstraction. All of him that the physicist finally deals with is what is common to the elephant and the pointer-readings; namely, a more abstract, a *very* abstract, configuration of relationships. This structure of relations is what, in general terms, the mathematical equations of physics express.

Thus if the last conceptual stage of the elephant – and of the physical in general – is in mathematics, or a set of relations of relata, it is not necessary to try to follow this transmogrification of the elephant, or of matter, with the

[11] Pp. 251 ff.

imagination. Nor is it appropriate to cry shame upon the physicist for leaving the world of palpable elephants in favor of such unimaginable abstractions. The physicist's concept represents simply an intermediate stage in a process which begins and ends with elephants and such – not with the physicist's elephant even, but the one which slid down the bank and got put in the box-car.

As Professor Dewey points out, the physicist and mathematician simply take this intermediate stage off by itself and deal with it on its own account.[12] Thus if we reflect upon the functional theory of knowledge, I think we may come to the conclusion that there is no implication of it which is incompatible with the notion that concepts in general are abstractions – are even very thin abstractions. Because the function of concepts is not to *photograph* elephants but to get them into box-cars. Concepts represent simply that operational function of cognition by which it transforms the something given, with which it begins, into the something anticipated or something done, with which it ends. That they may have lost, or discarded as irrelevant, those elements of the concrete and immediate which characterize direct perception and imagination, is nothing to the point. Goodness in a concept is not the degree of its verisimilitude to the given, but the degree of its effectiveness as an instrument of control. Perhaps Professor Dewey might even, with entire consistency, find fewer occasions to regret that the relatively undeveloped sciences of human affairs show a tendency to imitate this abstractness. When the social sciences attain that degree of abstractness, and consequent precision, which already characterizes physics and mathematics, perhaps they will have less trouble getting their social elephants into their social box-cars. Economics is the best developed of the social sciences, and a fair illustration.

To conclude: the fact that the pragmatic test seems, on the one hand, to demand that all meaning be found eventually in the empirical, and on the other, seems to induce a flight from the immediate and directly apprehensible into abstractions, is not, in reality, any contradiction or any difficulty. In one sense – that of connotation – a concept strictly comprises nothing but an abstract configuration of relations. In another sense – its denotation or empirical application – this meaning is vested in a process which characteristically begins with something given and ends with something done – in the operation which translates a presented datum into an instrument of prediction and control.

LOGIC AND PRAGMATISM

C. I. Lewis. "Logic and Pragmatism." *Contemporary American Philosophy: Personal Statements*, ed. George P. Adams and William P. Montague (New York: Macmillan, 1930), pp. 31–51.

The most powerful single influence in my intellectual development was an old lady whom I met when I was fifteen. A year or two earlier I had begun a period of the most intense and furious thinking I shall ever experience. The combination of native scepticism and an orthodox upbringing had proved to be an explosive mixture: I had been plunged into doubts and questions which went on and on until I faced the universe with something of the wonder of the first man. The old lady, with compassionate understanding, confessed that she too was a heretic, and after establishing our agreements we went on to the much more enticing matter of our disagreements. Our discussions continued, at intervals, over a period of about two years, at the end of which time I had worked out my own answers to the puzzles which beset me. Some of these, I am sure, must have startled and amused my mentor, but she always agreed solemnly to consider them.

As yet no book on philosophy had even fallen under my eye; but about this time someone must have said the right word, because I remember reading a short history of Greek philosophy (Marshall's, I think), and then, following the references, looking into Ueberweg and the Zeller books. My chagrin was enormous. Much of my philosophy had been anticipated by two gentlemen named Heraclitus and Anaxagoras, and the rest could be fairly duplicated by a judicious eclecticism amongst the other pre-Socratics. It was my first professional disappointment, and quite the most grievous. I read Spencer's *First Principles* also, and found there much of stimulus and much which broadened my horizons – so much, in fact, that I cannot now recall any sense of bewilderment or failure to understand. Very likely I did not comprehend enough of it even to be properly puzzled.

Nothing comparable in importance happened after that until I became acquainted with Kant. I was now safely under academic auspices, and thinking was no longer a lone adventure. Kant compelled me. He had, so I felt, followed scepticism to its inevitable last stage, and laid his foundations where they could not be disturbed. I was then, and have continued to be, impatient of those who seem not to face the skeptical doubt seriously. Kant attracted me also by his intellectual integrity and by the massiveness and artic-

ulation of his structure. The evidence of Kant in my thinking ever since is unmistakable, however little I may achieve the excellences which aroused my youthful admiration.

Of my teachers at Harvard, Royce impressed me most. His ponderous cogency kept my steady attention, even though I never followed to his metaphysical conclusions. James, I thought, had a swift way of being right, but how he reached his conclusions was his own secret. Royce was, in fact, my paradigm of a philosopher, and I was prone to minimize the difference from him of such convictions as I had. It was Royce himself, finally, with my doctor's thesis before him, who pointed out the extent of these differences. He concluded by saying, with his usual dry humor, "I thought you were principally influenced by Perry, but I find he thinks you are principally influenced by me. Between us, we agreed that perhaps this is original."

Royce was also responsible for my interest in logic, or at least for the direction which it took. In 1910–11 I was his assistant in two courses in that subject and he put into my hands one of the first copies of *Principia Mathematica*, Volume I, which came to Cambridge. It is difficult now to appreciate what a novelty this work then was to all of us. Its logistic method was so decidedly an advance upon Schröder and Peano. The principles of mathematics were here deduced from definitions alone, without other assumptions than those of logic. I spent the better part of a year upon it.

However, I was troubled from the first by the presence in the logic of *Principia* of the theorems peculiar to material implication, such as "A false proposition implies any proposition," and "A true proposition is implied by any." The theorems themselves, of course, were familiar; they went back to Peirce and Schröder. But in spite of Peirce's remarks on the topic, I had never taken them seriously, because of their obvious historical origin.

The investigations to which I was moved by this relatively small matter grew in scope and occupied such leisure as I had for the next six years. Moreover, my thinking on other philosophic topics has been much influenced by these researches, so that I must present, as briefly as possible, the gist of this problem.

Those logicians who were earliest interested in an exact calculus of logic had, all of them, turned first to the relations of concepts or classes. This necessitates a choice – as may be discovered by their mistakes – between the logic of intension and the logic of extension. The relations of class-names in intension are meagre in certain ways, and hardly afford a calculus. Boole founded the algebra of logic, where Leibniz and his Continental successors had failed, principally because Boole interpreted logical relations exclusively in extension. This is no particular merit of Boole's; it seems, rather, to result from the fact that he was born in Great Britain, and knew nothing about his Continental predecessors. British logicians, when really original, have always thought in terms of extension; Continental ones in terms of intension. (Some

psychologist with an eye for history ought to investigate this.) So Boole took the universal proposition, "All *a* is *b*," to mean, "The class of things *a* is included in the class *b*," instead of "The concept *a* includes or implies the concept *b*," as a Continental would have done. This extensional point of view requires the special case that if there are no members of the class *a*, then "All *a* is *b*" will hold, regardless of the connotations of *a* and *b*. If Boole had any misgivings about this paradox, the arithmetical analogies which he followed in constructing his algebra would have compelled it in any case. The null-class is contained in every class just as $0 < x$, for any positive number x. The converse principle, that any class is contained in the class of "everything," is obvious.

The effect of these limiting cases is to restrict the interpretation of the algebra as a logic of class-terms to the relations of extension. If there are no centaurs, then all the centaurs there are will be Greeks; this is true regardless of the connotation or intension of "centaur" and "Greek." It does not follow that if there *were* any centaurs they *would be* Greeks.

Now Boole discovered a second application of his algebra to propositions (more correctly, to propositional functions). For this, he let the symbols *a*, *b*, *c*,... represent the times when the propositions *A*, *B*, *C*, are true. Here the analogue of "All *a* is *b*" is, "Whenever *A* is true, *B* is true," or "*A* implies *B*." If the algebra is to have this second application, the properties of implication must be point for point analogous to those of classes in extension. Hence if $A = 0$ – that is, if *A* is always false – then *A* must imply any proposition *B* whatever. And if *B* is always true – that is, if $B = 1$ – then *B* must be implied by every proposition. Boole's principal successors, Peirce and Schröder, observed that a proposition, as distinguished from a propositional function, if once true is always true. Hence as applied to propositions, $A = 0$ may be interpreted simply as "*A* is false," and $B = 1$ as "*B* is true."

Thus the application of the algebra to propositions requires these two principles, "A false proposition implies anything" and "A true proposition is implied by any." In the sense of "implies," which figures in the algebra, "*A* implies *B*" will hold if *A* is false or if *B* is true, and will fail only when *A* is true and *B* is false.

As the analogy with classes shows, this is the case only because the algebra must be restricted to relations of extension. The relation here designated by "implies" is such that a false proposition implies anything, but that throws no light on what it *would* imply if it *were true*.

A meaning of "implies" which is such that the implications of a proposition depend upon its truth or falsity is certainly not the usual one. And the peculiar properties of it are neither important logical discoveries nor absurdities; they are merely the inevitable consequences of a novel denotation for an old and familiar word, long used in common parlance in a different meaning. Thus the calculus of propositions which is historically continuous with Boole is not

a calculus of implications, such as those with which logic and deduction generally have always been concerned. This new meaning of "implies" (now called "material implication") should be submitted to some examination before its laws are accepted as a canon of deduction. Such examination was lacking in *Principia*.

Two sorts of problems were before me. First and most obviously: Is there an exact logic, comparable to this extensional calculus, which will exhibit the analogous relations in intension? And is the intensional analogue of material implication the relation upon which deductive inference is usually founded? Second, there were larger and vaguer questions: Could there be different exact logics? If I should find my calculus of intension, it and material implication would be incompatible, on some points, when applied to inference. In that case, in what sense would there be a question of validity or truth to be determined between them? And what criteria could determine the validity of logic, since logic itself provides the criteria of validity used elsewhere, and the application of these to logic itself would be *petitio principii*?

Even the two questions of the first sort could not really be determined in separation from these more general problems. Yet I chose to begin with them. It seemed more promising to argue from exactly determined facts of the behavior of symbolic systems to conclusions on more general problems than to attempt to reverse this procedure. Logicians who argue from "first principles" to the validity or invalidity of logistic developments find themselves in a weak position, since they dogmatize about a matter which they either have not investigated or have approached with an initial prejudice which commits the *petitio principii* just pointed out.

Leaving, then, the larger questions, I turned to the logistic development of the logic of intension. The results of this investigation may be briefly summarized, since it has been outlined in Chapter V of the *Survey of Symbolic Logic*.[1]

The intensional implication relation (or "strict implication" as I called it) gives rise to a calculus as exact as the older logistic systems. It is also more

[1] A note should be added concerning the mistaken postulate which I there assumed for the system of strict implication. This was later pointed out by Dr. E. L. Post, and corrected by me in a note in the *Journal of Philosophy*. [Strict Implication – an Emendation." Vol. XVII (1920), No. II, pp. 300–302.] In developing the system, I had worked for a month to avoid this principle, which later turned out to be false. Then, finding no reason to think it false, I sacrificed economy and put it in. It was because it thus entered the system so late in its development that I was able, when the mistake was discovered, to correct it in brief space. The system of strict implication, as printed, contained no postulate logistically incompatible with a material interpretation, such as $?p\colon -p\ .\ -(p < -p)$. To include this would have required a fundamental complication, undesirable in a book addressed to beginning students. I am lately in receipt of a proof, made by a Polish student, M. Wajsberg, that the principle $p < .\ q < p$ is independent of the amended postulates. This covers the same point.

inclusive: when the extensional relations are introduced by definition, it includes the calculus of propositions, as previously developed, as a subsystem. While there are ambiguities about the usual meaning of "implies," and the final issues are such as have seldom been faced at all, on the whole accepted deductive procedures and ordinary logical intuitions accord with strict implication and do not accord with material implication where it diverges.

The only implication relation upon which inference is likely to be based is this intensional or strict implication, for reasons which are fairly obvious. "The proposition *A* materially implies the proposition *B*" means precisely, "It is not the case that *A* is true and *B* false." This is necessary to ordinary deduction, since otherwise false conclusions could be derived from true premises, but it is not sufficient. To see this, let us inquire how this relation might be verified as holding. In a particular case, it could be verified simply by finding *A* to be false; but that would mean finding our premise false, so that the conclusion *B* would ordinarily not be drawn. Sometimes, however, we are interested to draw the inferences from false assumptions. But we should not do this on the basis of material implication, precisely because a false premise materially implies anything and everything. That *A* materially implies *B, because A is false*, throws no light on the question what *A would* imply if it *were true*.

We might also verify "*A* materially implies *B*" in a concrete instance by finding *B* to be true. But this would mean finding our conclusion to be true. Most frequently in such cases we should not "make the inference" because it would be superfluous. Sometimes, however, we are interested to discover what implies some known fact and what does not – for example, in the testing of hypotheses. But a known fact is *materially* implied by *any* hypothesis. Amongst known facts, the material implications of all hypotheses whatever are identical.

Consequently no use can be made of material implication in drawing valid inferences, except in those cases in which the implication can be known to hold for some other reason than that the premise is false or that the conclusion is true. When we inquire how we can know that it is not the case that *A* is true and *B* false, without knowing that *A* is false and without knowing that *B* is true, the only answer is: By knowing that if *A were* true, *B must be* true; by knowing that the truth of *A* is inconsistent with the falsity of *B*; by knowing that the situation in which *A* should be true and *B* false is an impossible situation. That is to say, the only case in which any inference could be based on a material implication is precisely the case in which it should coincide (and *be known* to coincide) with the intensional or strict implication of *B* by *A*. This amounts to saying that the real basis of the inference is the strict implication. "*A* strictly implies *B*" mean exactly "The truth of *A* is inconsistent with the falsity of *B*."

The so-called "formal implication," "For every x, ?x materially implies ?x," would coincide, in its general deductive significance, with strict implication provided "For every x" be interpreted to mean "For every possible or conceivable x." It will be obvious that "For every conceivable x, it is not the case that ?x is true and ?x false," is a strict implication, differently phrased. But if "For every x" means "For every x that *exists*," then this formal implication represents the ordinary relation of classes, "Every existent thing having the property ?, has also the property ?." In *Principia* it is this second interpretation of formal implication which is chosen.

Various technical problems which came to light in the course of these investigations may be omitted here as probably of small interest to the general reader. However, there is one such matter which must be mentioned because it influenced the direction of my thinking outside the field of exact logic. Early in the course of these researches I formed the conviction that all valid inference, being a matter of intension, rests upon the analysis of meaning. The reasons for this will probably be evident from the foregoing. But the symbolic relations I was dealing with proved to have properties which I had not anticipated, and some of these gave me pause. In particular, while it would not be true, in the system of strict implication, that a merely false proposition implied anything and everything and a merely true proposition is implied by any, it *would* hold that a "necessary" proposition (defined as one which is implied by its own denial) is implied by any, and that a self-contradictory proposition (one which implies its own denial) implies anything.

Had I made a mistake in my assumptions so that the system was out of accord with the properties of analytic inference? Or did the implication relation of ordinary inference have these properties? The latter proved to be the true alternative. There was no way to avoid the principles stated by these unexpected theorems without giving up so many generally accepted laws as to leave it dubious that we could have any formal logic at all.

There were many corroborations. The simplest to set down is as follows: Suppose that a proposition A (say, "Today is Monday") implies another, B ("Tomorrow is Tuesday"). Then the premise A, together with any additional proposition, C (say, "Mars is not inhabited"), will likewise imply B – that is, "Today is Monday, and Mars is not inhabited" implies "Tomorrow is Tuesday." According to another general principle, if two premises give a conclusion, but that conclusion is false while one of the premises is true, the other premise must be false. "All men are mortal" and "Socrates is a man" together imply "Socrates is mortal." Hence if all men are mortal, but Socrates is not mortal, then it follows that Socrates is not a man – that is, we have the rule: If "A and C" implies B, then "A but not B" implies "not C." Applying this rule to our first example, we have: "Today is Monday and Mars is not inhabited" implies "Tomorrow is Tuesday"; hence "Today is Monday, but tomorrow is not Tuesday" implies "Mars is inhabited." In this illustration,

the last-mentioned proposition might have been anything you please without altering anything else. Thus ordinary logical conceptions require that the affirmation of a premise, together with the denial of its consequence (a case of contradiction), will imply anything and everything.

If, then, I had made no mistake, the line of division which marks off that class of propositions which are capable of corroboration by logic alone (necessary propositions) from merely empirical truths, and marks off the impossible or absurd, which can be refuted by logic alone, from merely empirical falsehood, is a division of major importance. Possible and impossible, contingent and necessary, consistent and inconsistent – such categories of intension are independent of material truth, and their distinct nature is founded in logic itself. Moreover, as is easily obvious, all the propositions of logic are truths of intension, and therefore certifiable without reference to the merely factual or empirical.

But I had further doubts. In particular it was not clear that if one should, by inadvertence, set out with incompatible assumptions, there would be no conclusion whatever which one might not draw from them by analytic inference. Nor was it clear that all necessary propositions are analytically derivable from any assumption you please. The facts of the symbolic system were inescapable, and ordinary practice corroborated them; but what did these facts mean?

In part, the answer was a simple one which should have been anticipated. These unexpected properties of implication did not mean that all necessary propositions are analytically derivable from any arbitrarily chosen assumptions whatever; they did represent the fact that implication is not a property of isolated propositions as such, but of systems. Necessary truths are all of them principles of logic, or such as can be certified on grounds of logic alone. Without logic, nothing is derivable from anything; the logic of it is implicit in every deductive system. All necessary propositions are thus, explicitly or tacitly, present in every system, and indeed in every assertion conceived as having logical consequences. Inference is analytic of the system rather than of its separate and bare constituents. If there is any exact logic which is capable of representing inference as analytic in any other sense, I have never been able to discover a clue to it. I should but be dumbfounded to learn of such tomorrow, but I have followed every lead that has occurred to me, always with negative results.

If inference is analytic of systems, not of propositions in isolation, does this mean that logic compels the acceptance of a coherence theory of truth or the acceptance of that kind of unity of the world which is maintained by logicians of the "modern" or Hegelian school? I turned briefly to the consideration of this possibility – though, I must admit, without any conviction of the necessity of so doing – because while it had become apparent to me that logic required the existence of necessary propositions, it was not so apparent that it required

the existence of any truth which is *not* necessary. That the distinction of necessary and contingent must finally fail and all truth reveal itself as necessary, because inference depends on systematic unity, is just what the modern logicians claim. The conclusions which I reached are outlined in a little paper, "Facts, Systems, and the Unity of the World." The thesis that all truths are necessary, and none independent of any other, is hopelessly implausible in the light of certain facts of mathematical systems concerning which nobody (unless it be the modern logicians themselves) has ever entertained a doubt. The whole development of modern geometry, for example, must be somehow invalid if they are right.

The most general and important issue was still before me. I had set out to determine a question of truth between two symbolic systems – material implication and a logic of intensional implication. This had raised the further question what kind of an issue of truth there could be in such a case, and what criteria could determine it. I had found, in commonly accepted practices and principles, corroboration of the characterizing features of strict implication – the distinction of necessary from contingent truth, the classification of logical principles themselves as necessary, and, as a consequence, the status of logic as self-affirming or self-critical, its principles being implied by their own denial. Could such necessity or self-affirmation be accepted as a final criterion of truth in logic?

There was unmistakable evidence that such was not the case. In the first place, both material implication and strict implication had this character, yet both could not be accepted as stating the truth about what can validly be inferred from what – the truth of logic. Also I found that other and somewhat similar systems could be devised, each of which would have the same general kind of mathematical precision and methodological integrity. These might be called "pseudo-logics" or "metalogics." Though I made no systematic investigation, it became evident that the number of such would be limited only by some criterion of "logistic system" or of the principles of derivation which should be allowed. Such a criterion would itself be an antecedent principle limiting "logical" truth. That such a system might be totally unacceptable as a "true logic" and yet be entirely consistent, and even self-affirming, in its own terms is due to the curious involution which is peculiar and inevitable to logical truth. "Consistency" is the absence of an "implication": two propositions are consistent when neither implies the negation of the other. Hence if the meaning of "implies" – and consequently the methods of derivation – be allowed to vary, a "queer" logic may be "consistent" or "self-critical" in its own "queer" way.

Thus we revert to the previous question, which now assumes a somewhat complicated form. If formal logic is capable of any exact development at all, then we are confronted with the task of deciding which, amongst various possible and actual logistic systems, is such that its principles state the truth

about valid inference. Internal consistency and "self-criticism" are not sufficient criteria to determine a truth which is independent of initial assumptions which are they logical in nature. Thus logic cannot test itself – or rather, such test does not prove truth in logic.

It was clear that such a problem has no solution in logic; I was carried beyond logic into the field of epistemology. Many other strands, not mentioned here, were, of course, already woven into my thinking. In particular it had been impressed upon me that it is possible to take symbolic procedures both too seriously and too lightly. To paraphrase Hobbes: Symbols are our counters; they are the money of fools. But on the other hand, the behavior of symbolic systems is nothing more or less than the behavior of the human mind, using its most characteristic instrument: there is nothing in them which we have not put in ourselves, but they teach us inexorably what our commitments mean.

Also, at just this time it became my duty and privilege to turn over the numerous unpublished papers of Charles Peirce. Though I was not especially conscious of it, this was perhaps the means of stirring up old thoughts of the time when I had listened to James, and reminding me also of what Royce used to call his "absolute pragmatism." Again, I had long been attracted to certain theses of Dewey's logic – if only he would not miscall "logic" what is rightly a much wider thing, the analysis of the constructive thought-process! The study of exact logic itself had revealed unmistakably that in every process of reasoning there must be an extra-logical element. This cannot but be so, since from any premise or set of premises whatever an infinite number of valid inferences can be drawn. (This is an immediate consequence of Poretsky's laws.) What is called "*the* conclusion" must be selected from this infinity by psychological obviousness or by some purpose or interest; certainly logic does not dictate it. The *direction* of thought inevitably belongs, then, to such an extra-logical factor. Finally, Peirce's "conceptual pragmatism," turning as it does upon the instrumental and empirical significance of concepts rather than upon any non-absolute character of truth, was at some points consonant with my own reflections where James and Dewey were not.

Whatever it was that turned my thoughts in this direction, at any rate I began to see that the principles of logic will answer to criteria of the general sort which may be termed pragmatic, and that where empirical verification is not in point, and logical "necessity" itself is not sufficient, no other kind of criterion can in any sense be final.

It had become apparent from my little experiments with strange "logics" that two minds which followed different systems in their modes of inference need not be unintelligible to one another – that, in fact, they might be so related that when their premises were common neither (outside of logic itself) would ever reach a conclusion which the other must repudiate as false. But, as between two such, the road from premise to conclusion would be more or

less direct, more or less impeded. Fundamental psychological bent might here dictate a choice. Or again, if the general course of experience were other than it is – if, for example, all processes in nature should be reversible – then, although no different choice of modes of inference would be dictated, a different "logic" would apply with more facility. Thus the ultimate ground of accepted logical principles, as against other self-consistent modes, might be criteria of convenience (a poor word, but the best I can think of), somewhat like those which Poincaré suggested as determining our choice of Euclidean geometry.

This thesis, by itself, seems implausible and highly paradoxical: the stronghold of pragmatism supposedly lies in the empirical; logic is the citadel of rationalism. Nevertheless I became more and more convinced that this was right. Pragmatism, as ordinarily understood, seems to take things wrong end on; it is the element which mind contributes, in truth and knowledge, which may be pragmatic; the empirical brute fact of the given is absolute datum. Logic contains no material truth; it is independent of the given precisely because it dictates nothing whatever with regard to the content of experience, but determines only the mind's mode of dealing with it. This thought suggested others, which soon came to keep it company and mitigate the paradoxical air which it exhibited in isolation.

A variety of other problems, mainly in the theory of knowledge, had been in my mind for the past few years. Some of them were closely related to those already suggested as growing out of logic. I now sat down (this was in 1921) to the first draft of something concerning these, which I projected as "Studies in Logic and Epistemology." These will never see the light. They grew from one box to two, and then to several. But the yeast of the newly awakened pragmatic conceptions was working too strongly. My thought changed and widened as I attempted to formulate it, and the result, instead of moving toward some unity of subject and literary coherence, spread in widening circles through the whole field of philosophy. It was a most satisfactory period to me personally, because in the course of it I squared my account with many problems and brought them into touch with one another. What I shall venture to call "conceptualistic pragmatism" proved to be, for me, the key that opened many doors. But my notes I put away, except for a relatively small portion, and concentrated upon certain closely related topics which I found myself particularly interested to develop further. The attempt to outline some of these is the remaining task of this paper.

Logic, and that which is certifiable on logical grounds alone, constitutes the *a priori* element in knowledge. The Kantian cross-classification, by which *synthetic* judgments *a priori* become the foundations of science, has more and more clearly been proved to be without foundation, as mathematics and exact science have developed. Mathematics has been shown to be capable of purely logical development, by analysis alone, and without

recourse to any synthetic element, such as geometric constructions, which represent an appeal from pure conception to intuition. *Principia Mathematica* represents the final stage of the movement in this direction: we see here the deductive development of mathematics merely from the logical analysis (definition) of the mathematical concepts. There is and must be a synthetic element in judgment about the *applications* of mathematics, about real space, or about concrete collections of things. At the same time that mathematics becomes purely logical and analytic, it becomes abstract. Which of the various abstract geometries applies to space becomes a separate and extra-mathematical question, and, as Poincaré and relativity have shown, one which is to be determined either upon empirical grounds – in which case the answer is probable only – or by some pragmatic choice, or by some interplay between these two.

Hume was right in his somewhat wavering conviction that the truths of mathematics represent necessary connections of ideas, and likewise right that this by itself does not prove any necessary connection of matters of fact. The line between the *a priori* and the *a posteriori* coincides with the division between conceptual and empirical; and it likewise coincides with the distinction between what mind itself contributes or determines and what is given as datum of sense.

A priori truth is independent of experience because it is purely analytic of our conceptual meanings, and dictates nothing to the given. Logic, mathematics, and in general whatever has structure and order and system may be developed in abstraction from all consideration of the empirical by purely logical analysis. It depends upon nothing but its own conceptual integrity for that kind of truth which is possible to abstract systems.

Such *a priori* truth is not assertive of material fact, but definitive. This is the clue to many problems. In the first place, it exhibits clearly the sense in which we can make stipulations applicable to experience but independent of its content. In the absence of definitive criteria, experience would be unintelligible; these are prerequisite to truth and knowledge, though not to mere givenness. The definitive principle is "necessary" truth: it cannot be false; it is prerequisite to intelligibility; it must be taken in advance of the particular experience; it dictates nothing as to the content of the experience.

In the second place, this solves the problem of the criterion between what mind contributes in truth and knowledge and what is independent of the mind. How should we know what mind does, if mind could do no different? I discover what I do solely by the difference in what ensues when I refuse to do, or do differently. If there should be immutable and "un-get-over-able" modes of intuition or of thought, the mind could never discover that these belonged to itself and were not characters of the independent real; they would be absolute data, flatly given in experience, and the individual would find them as he finds his ears.

There must, then, in some sense or other, be conceivable alternatives to what is *a priori.* In those modes of our own intellectual activity which are exhibited in the criteria supplied by definitive principles, there are such alternatives. A definition may be laid down in one or another way; we classify and order and understand as we ourselves determine. Once our exact concepts are taken, the unfolding of them is an absolute truth: there is no alternative about that (unless we ascend to some higher choice of alternative modes of deductive order itself). But what concepts we shall formulate, and what we shall apply, admits of choice. The mind approaches the chaos of experience with its own intellectual instruments, which are independent of the given as the given is of them. Truth and knowledge represent the meeting of these two. That the particular truth and knowledge may reflect, in some part, a choice of such instruments, that the net of understanding may be stretched across the given in terms of one or another reference system of conceptual order, is a matter which might well be illustrated at some length, but will probably be evident without such exemplification. And the sense in which the truths of experience will be, on one side, determined by the presence of such definitive conceptual order, though the content of the given is not thus determined, will likewise be clear. The whole trend of exact science serves strongly to enforce the fact of this presence, throughout all knowledge, of an *a priori* element which enters through the simple fact that experience never supplies its own conceptual interpretation, but that conceptual systems, amongst which there may be possible choice, serve as criteria of such interpretation, without imposing any limit on the empirical content. That in the presence of such alternative systems of order, pragmatic criteria, which may reflect on the one side human bent and interest, and on the other a facility determined by the general character of what is presented, will have their place in fixing the truths of experience, needs no special demonstration.

If, however, all truth which can be certain in advance of the experience to which it applies is of this purely analytic and definitive sort, then we might be led to remark that such abstract *a priori* truth tells us nothing of the nature of reality beyond our own minds, and is significant only of our own consistency of thought. This conclusion would be a mistaken one; paradoxical as it may sound, we can predict the nature of reality without prescribing the character of future experience. What the mind meets in experience is not independent *reality*, but an independent *given*; the given is not, without further ado, the real, but contains all the content of dream, illusion, and deceitful appearance.

In fact, the criteria of reality represent a peculiarly illuminating example of the *a priori.* The word "real" has a meaning, and represents a definite conception which, when applied to the content of experience, leads to the interpretation of this content sometimes as "real," sometimes as "unreal." The formulation of the criteria of the real constitutes a merely analytic or defin-

itive statement, representing our interpretative attitude. Such criteria of reality can neither be supplied by experience (since direct generalization from an unsorted experience, not already classified as real, would not serve) nor can experience invalidate them. Whatever in experience does not conform to the criteria of reality is automatically thrown out of court.

We can and must prescribe the nature of reality. We cannot prescribe the nature of the given. The paradox of this is mitigated somewhat when we observe that the word "real" is systematically ambiguous. "Reality" is of different sorts, physical, mental, mathematical – the easily named categories do not cover the easily recognized distinctions. A mirror-image, for example, is its own particular kind of reality, neither "physical" nor "mental," as is also a mirage and "appearances" in general. Each category of reality has its own peculiar criteria, and what is unreal in one sense will be real in some other. *Any* content of given experience will be real in some category or other – will be that kind of reality which is ascribed to it when it is "correctly understood." The categories are neither a Procrustean bed into which experience is thrust nor concepts whose applicability depends on some pre-established harmony between the given and the mind. Rather they are like the reference system which the mathematician stretches through all space and with respect to which whatever positions and motions are there to be described will inevitably be describable. Categorical criteria are neither insignificant and verbal tautologies nor empirical prophecies but exhibit definitive criteria of intelligent classification and interpretation.

The content of a properly conceived metaphysics is the analytic truths which exhibit the fundamental criteria and major classifications of the real; it is definitive of "real"-ity, not descriptive of the universe *in extenso*. In fact, all philosophy has for its task such analytic depiction of the *a priori* – to define the good, the right, the true, the valid, and the real.

It will be evident that the absoluteness of such *a priori* principles, whenever and wherever they are held, is entirely compatible with their historical alteration, just as modes of classification or alternative reference systems, expressible in definitive principles or initial prescriptions, would be absolute while adhered to, but might be subject to considerations of usefulness and to historical change. The assurance of perpetuity for our categories is no greater than the assurance that our basic human nature and the broad outlines of experience will never alter. There is an eternal truth about our abstract concepts – the given is absolute datum; but the chosen conceptual systems applied to the interpretation of the given are subject to possible change. In the field of metaphysical concepts particularly, such change would seem to be a fact – as the history of such concepts as "matter," "mind," and "cause" bears witness.

The categories differ in no wise from concepts in general except in degree of comprehensiveness and fundamental character. Every concept whatever

exhibits criteria of its own little kind of reality. In so far as experience is intelligible and expressible only when grasped in some framework of conceptual interpretation, this *a priori* element of the definitive is all-pervasive.

It is the conceptual order of experience alone which is communicable or expressible. The given, apart from such conceptual interpretation, is ineffable. If, so to speak, one sensory quality could be lifted out of the network of relations in which it stands and replaced by another, the esthetic character of experience might be altered, but everything which has to do with knowledge and with action would remain precisely as before. Community of thought and knowledge requires community of concept or of relational pattern, but if there should be idiosyncrasies of sense which do not affect discrimination and relation, these would be immaterial to our common understanding and cooperation. In fact, in the face of all those *verifiable* differences of sense which are evidenced by our different powers of discrimination, we possess a common understanding and a common reality through the social achievement of common categories and concepts. When the vast and impressive institution of human education – in its wider sense – is remarked, the assumption that such community is simply native or ready-made is seen to be superfluous. My world is my intellectual achievement; our common world, a social one. The frequent objection of the sceptic, that knowledge is implausible in view of the subjectivity of sense, is an *ignoratio elenchi.*

Knowledge grasps conceptual structure or order alone. It was Berkeley who, almost without noting it himself, first phrased this nature of our knowledge. One idea is "sign of" another in the order of nature. If it be a reliable sign – that is, if it bear constant and orderly relationships – one empirical *quale* is as good as another to serve this function of cognition. Knowledge of the external world consists of relations between one item of experience and another, not in the content of experience somehow matching the quality of an external real. Such qualitative coincidence of idea and object – if the notion means anything – would be extraneous to knowledge. This conclusion is quite independent of idealism.

There are not two kinds of knowledge – one of principles or relations, expressible in propositions, and another which we have by mere presentation of the object. The conceptual interpretation of the given is the implicit prediction of other possible experience. As Mr. Whitehead has pointed out, no object can be known without reference to some temporal spread. My knowledge of the object is not the mere having of this presentation, but the implicit prediction of the eventuation of other experience continuous with this. What is thus predicted is not at the moment verified, but it must be verifiable if the interpretative concept is veridically applicable. The mere naming of this thing I see as "desk" predicts eventualities of a specific sort, which, if they should fail to be realized, would lead to the repudiation of the concept "desk" (or perhaps even of "physical reality") as inapplicable to this which

I see. The knowledge of any object transcends its given presentation and grasps a structure of experience. Without order, there can be no *thing*, no experience of *reality*. This, in brief, is the deduction of the categories.

That *if* this be a desk it *will be* thus and so, is an analytic consequence of the concept "desk," not subject to any falsification by experience. That any given "this" is really a desk is theoretically not completely certain. Thus there is an *a priori* element which is all-pervasive in knowledge and prescriptive of reality. Yet all empirical truth, without exception, is probable only.

One further note I should like to make in closing. As the word "knowledge" has been used above, it is narrowed somewhat from its usual meaning. It comprises what have sometimes been called the "truths of description" which, as it is here conceived, depend exclusively upon conceptual order. It excludes "truths of appreciation," the esthetic quality of the given, and all that depends upon sympathy and upon that communion of minds which requires coincidence of immediate experience. Evaluation can hardly be indifferent to the quality of the given. Nor can the basis of ethics be laid without reference to the felt character of experience in another mind. And the religious sense, if it is to take reality as the matrix of human values, will likewise transcend the interests of knowledge in this restricted sense. There is, then, a line of division between such interests and cognition of the type of science. And it is suggested that the foundation of these, not being found in knowledge alone, may rest upon some postulate.

EXPERIENCE AND MEANING

C. I. Lewis. "Experience and Meaning." *Philosophical Review* 43.2 (March 1934): 125–146.

The presidential address to the eastern division of the American Philosophical Association at Amherst College, December 29, 1933.

Ever since the provisional skepticism of Descartes' First Meditation the attack upon any problem of reality has always been shadowed by the question "How do you know?" The extent to which this perennial challenge has determined the course of modern philosophy requires no exposition. That on the whole the results of it have been salutary will hardly be denied; though it may be said – and has been said – that it leads, on occasion, to the confusion of methodological considerations with positive conclusions. The last thirty-five years have witnessed a growing emphasis upon another such challenge, which bids fair to prove equally potent in its directing influence. This is the question "What do you mean?" asked with intent to require an answer in terms of experience. That is, it is demanded that any concept put forward or any proposition asserted shall have a definite denotation; that it shall be intelligible not only verbally and logically but in the further sense that one can specify those empirical items which would determine the applicability of the concept or constitute the verification of the proposition. Whatever cannot satisfy this demand is to be regarded as meaningless.

For any sufficient consideration of this empirical-meaning requirement it would be essential to sketch those developments which have brought it to the fore: pragmatism and the "pragmatic test"; neo-realism, both of the American school and the similar view of Russell; the new methodology in physics which came in with relativity, especially Einstein's treatment of definition and Bridgman's operational theory of the concept; Whitehead's method of "extensive abstraction," by which certain previously refractory concepts can now be defined in terms of the actually observable and their empirical content thus made evident. Last and most particularly, one would mention the logical positivism of the Vienna Circle, whose program is based throughout upon this consideration of empirical meaning. It would likewise be desirable to consider the divergences between these different movements of thought in their interpretation of the general requirement of empirical meaning.

But before this audience it will be unnecessary to attempt any such survey, either of this development in current theory or of the points of divergence with respect to it. Taking these matters for granted, the purpose of what follows will be to explore a little certain questions concerning the limitations imposed upon significant philosophic discussion by this requirement of empirical meaning; in particular certain issues which are likely to divide those who approach these problems with the thought of James and Peirce and Dewey in mind from the logical positivists. The ultimate objective of such discussion would be to assess the bearing of this limitation to what has empirical meaning upon ethics and the philosophy of values, and upon those metaphysical problems which concern the relation between values and reality. But that objective cannot be reached in the present paper, which will be concerned with prior questions. Even these cannot be set forth with any thoroughness; and I hope it will be understood that the purpose of this discussion is to locate issues rather than to dispose of them, and that criticisms ventured are not put forward in the spirit of debate.

The Vienna positivists repudiate all problems of traditional metaphysics, including the issue about the external world supposed to divide idealists from realists, and any question concerning the metaphysical character of other selves. In the authoritative statement of their position we find the following: "If anyone assert 'There is a God', 'The ground of the world is the Unconscious', 'There is an entelechy as the directing principle in the living', we do not say to him 'What you assert is false' but instead we ask him 'What do you mean by your statement?'. And it then appears that there is a sharp line of division between two kinds of propositions. To the one belong statements such as those made in the empirical sciences: their meaning can be determined by logical analysis; more specifically, it can be determined by reduction to statements of the simplest sort about the empirically given. The other class of propositions, to which those mentioned above belong, betray themselves as completely empty of meaning, if one take them in the fashion which the metaphysician intends.... The metaphysician and the theologian, misunderstanding themselves, suppose that their theses assert something, represent matters of fact. Analysis shows, however, that these propositions assert nothing, but only express a sort of feeling of life."[1] According to Carnap all value-theory and normative science are likewise without meaning, in the theoretical or empirical sense of that word.[2]

[1] *Wissenschaftliche Weltauffassung des Wiener Kreises* (1929) 16. (I have translated somewhat freely.)

[2] "Auf dem Gebiet der Metaphysik (einschliesslich aller Wertphilosophie und Normwissenschaft) führt die logische Analyse zu dem negativen Ergebnis, dass die vorgeblichen Sätze dieses Gebietes gänzlich sinnlos sind." "Uberwindung der Metaphysik durch logische Analyse der Sprache," *Erkenntnis* II (1931) 220.

The expression of such feeling of life, and of our evaluative reactions, is, of course, admitted to be a legitimate and worth-while activity; but, as such expression, metaphysical theses are to be classed with art and poetry. Obviously there is room in such a theory for descriptive ethics, on a psychological or sociological basis, and for the determination of values by reference to a norm which is assumed or hypothetical; but traditional questions of the 'objectivity' of value are repudiated. We may meaningfully ask "When is a character judged good?" or "What is actually approved?" but not "With *what right* is this character said to be 'good'?" or "What is absolutely *worthy* of approbation?"[3]

This repudiation of metaphysics and normative science by the logical positivists cannot, I think, be regarded as an implication of the empirical-meaning requirement alone. At least an important light is thrown upon it by taking into account that "methodological solipsism" in accordance with which their program is developed. Even though they regard this procedure as advantageous rather than prescribed, still the negations or limitations which characterize it seem to underlie their theses, in whatever terms expressed.

On its constructive side this method means no more, at bottom, than a persistent attempt so to define the different classes of objects of our knowledge that the basis of this knowledge in direct experience will be exhibited. It is of the essence of knowledge that it is in the first person. Your mind and your experience can be nothing more, for my cognition, than a construction which I put upon certain data of my own experience. If, then, we are to have a thorough and completed account of knowledge, it is not sufficient that the constitution of objects known should be traced back to experience in the merely generic sense. So far as your observations and reports enter into the construction of that reality which is known to me, they can do so only through the interpretation which I put upon certain modes of your behavior perceived by me. Actually given experience is given in the first person; and reality as it is known in any case of actual knowledge can be nothing, finally, but a first-person construction from data given in the first person.

Consonantly, we have such construction of the objects of science in general as is outlined in Carnap's *Logischer Aufbau der Welt*: first, the different kinds of for-me entities (*eigenpsychische Gegenstände*) which are constructed out of elementary experiences (*Elementarerlebnisse*), at bottom, through the relation of remembered similarity (*Ähnlichkeitserinnerung*); second, physical objects, which are constructions out of the simpler for-me things of actually given experience; third, other selves and the mental or cultural in general (*fremdpsychische und geistige Gegenstände*), which are, for actual knowing, constructions out of certain classes and certain relationships of physical things and processes.

[3] See M. Schlick. *Fragen der Ethik*, esp. I 8 pp. 10–12.

In this program we have a consistently maintained effort to be true to the nature of knowledge as we find it. The egocentric predicament is taken seriously; and the "solipsistic" character ascribed to knowing is no more strange or fantastic than Kant's transcendental unity of apperception. The manner in which the *negative* side of logical positivism is related to this same method may, perhaps, be more readily appreciated by reference to cruder but somewhat parallel considerations which are suggested by Berkeley's argument against material substance. (It was Berkeley who first adduced the requirement of empirical meaning in order to prove his opponent's concepts empty and non-significant.)

As has often been noted, the significance and applicability of Berkeley's argument does not leave off at the point where he ceases to use it. By identical logic other selves and the past and future must go the same way as material substance. If you are more than one of my ideas, how can I know it? How can I consistently suppose that I even have an interest in that untouchable you outside my mind which *ipso facto* could make no difference in my experience of you? Also, at this moment, what is that past which I remember, as more than the present recollection, or the future as more than the present experience of anticipation? All must finally dissolve into the eternal now of actually given experience.

There is even one further step for this logic to take. What am I? This self as a recognizable or conceivable particularity can be no more than one of those ideas I call mine. And Wittgenstein gives indication that he accepts the parallel methodological implication: "The subject does not belong to the world but it is the limit of the world. *Where in* the world is a metaphysical subject to be noted? You say that this case is altogether like that of the eye and the field of sight. But you do *not* really see the eye. And from nothing *in the field of sight* can it be concluded that it is seen from an eye.... Here we see that solipsism strictly carried out coincides with pure realism. The I in solipsism shrinks to an extensionless point and there remains the reality coordinated with it."[4]

I must not convey the impression that the logical positivists use Berkeleyan arguments, or that they arrive at their conclusions by such a train of thought as the above. Nevertheless this may serve to suggest how methodological solipsism comports with a thoroughgoing empiricism; and it further suggests why this procedure is to be taken as having no metaphysical implications. Subjective idealism, consistently carried through, ends by qualifying every substantive with the prefix "idea of" or "experience of," which by being thus universal becomes meaningless. Whereas Berkeley supposes his argument to

[4] *Tractatus Logico-Philosophicus*, pp. 151–153. *Cf.* Carnap, *Logischer Aufbau der Welt* §65.

establish a subjectivist metaphysics by proving the realistic metaphysics to be empty of empirical meaning, logical positivism points out that the contrary of a meaningless assertion is likewise without meaning, and hence repudiates metaphysical theses of both sorts, and the issue itself, as non-significant. Three points, here evident, contain, I think, the gist of the matter. First; when knowledge is envisaged, as it must be, from within the egocentric predicament, all objects known or conceived must reveal themselves as constructions, eventually, from data given in first-person experience. Also, what enters into such construction from past experience can only come in by way of present recollection. (This last is, I take it, the reason for the basic position of the relation of remembered-similarity in the program of Carnap.) Other selves and their experience, or their reports, can enter only as certain items of first-person experience upon which a peculiarly complex construction is put. Second; distinctions such as that between real and imaginary, or between that which is apprehensible to me alone and the object apprehended by us in common, must nevertheless find their genuine place and importance in such construction. The fact that we make these distinctions in practically useful ways evidences that they are not outside the egocentric predicament and metaphysical but inside it and empirical. They are determined by criteria which the subject can and does apply within his own experience. Berkeley, for example, offered the criterion of independence of my will as the basis for the distinction of real from imaginary. And in Carnap one finds such distinctions, and their empirical criteria, meticulously examined. Third; metaphysical issues concerning the external world and other selves do *not* turn upon such empirically applicable distinctions as those just referred to, which can be applied within first-person experience. Such metaphysical issues can arise only as it is attempted to give some second meaning to the concepts involved; meanings which do not answer to any empirical criteria which the subject can apply within his own experience. Throughout, a particular and critical point is that only first-person (*eigenpsychische*) data of experience are allowed, in the end, to enter into the construction of objects of knowledge or to function as the empirical content of any meaning.

There is, I think, one further question which is crucial for any theory of knowledge; namely, the question of immediacy and mediation, or transcendence. This has a connection with the preceding considerations; but with respect to this further problem I cannot satisfy myself that I elicit any complete and clear pronouncement from the literature of logical positivism. One can pose the principal issue involved by reference to a statement of Russell's: "Empirical knowledge is confined to what we actually observe."[5] This may seem to be a truism; but I think it is in fact thoroughly false, and demonstrably

[5] *Our Knowledge of the External World*, p. 112. The author makes this statement quite in passing, and perhaps without having in mind the point with which we are concerned.

incompatible with the very existence of empirical knowledge. Let us impose this limitation quite rigorously, in conformity with the considerations set forth above. Knowledge is always in the first person; whatever is known must be known to the subject in question, at the actual moment, within his own experience. The experience of others can enter only as certain items of their subject's own – their reports and behavior perceived by him. And the experience of yesterday or tomorrow can figure in this knowing only as it enters, in the form of memory or imagination, into experience here and now. Hence nothing can be known but what is verifiable in the subject's own experience at the moment when the knowing occurs.

Similarly for meaning. Suppose it maintained that no issue is meaningful unless it can be put to the test of decisive verification. And no verification can take place except in the immediately present experience of the subject. Then nothing can be meant except what is actually present in the experience in which that meaning is entertained. Whatever runs beyond this is unverifiable, and hence meaningless. The result of any such train of thought is obvious; knowledge would collapse into the useless echo of data directly given to the mind at the moment, and meaning would terminate in the immediate envisagement of what is meant.

This is a reduction to absurdity of both knowledge and meaning.[6] If nothing can be known but what is literally within the cognitive experience itself, and what is meant can be only that which is present in the experience which is the bearer of that meaning, then there is no valid knowledge and no genuinely significant meaning. Because the *intention* to refer to what transcends immediate experience is of the essence of knowledge and meaning both. Berkeley himself tacitly recognized that, in noting that one idea is "sign of" another which is to be expected; even the skeptic recognizes this intent of knowledge – he is skeptical precisely of the possibility that what is *not* immediate can be known. If that intention of transcendence is invalid, then the further characters of knowledge and of meaning are hardly worth discussing.

Neither the logical positivists nor anyone else (unless a mystic) intends this reduction to absurdity. But if it is something which has to be avoided by any theory which is compatible with the genuine validity of knowledge, that fact becomes important for the just interpretation of the requirement of empirical meaning. In particular, it becomes evident that the experience in terms of

[6] In order to avoid confusion with a quite different problem, the distinction between meaning in the sense of denotation and meaning as connotation should be in mind. It is only the former meaning of "meaning" which is in point in this discussion. In the classification of logical positivism meanings are (1) structural, as in logic and mathematics, or (2) empirical, as in natural science, or (3) emotive, as in art and poetry. It is meaning in sense (2) which is concerned here.

which a cognitive meaning requires to be explicated cannot be exclusively the subject's own given data at the moment of the cognition. Thus that manner of reading the implications of methodological solipsism which is suggested above would condemn that procedure to futility. If what the method requires is that objects known should be constructed or defined exclusively in terms of sense-data actually given to the subject at the moment when the knowing takes place, then that method is incompatible with the possibility of knowledge and the reality of empirical meaning.

We are here faced with a problem which runs through the whole history of post-Kantian epistemology – though it is Berkeley rather than Kant who precipitated it in its modern form. How can the knowledge-relation, or the relation of idea to the object it denotes, be valid unless what is known or meant is present to or in the experience which knows or means? But if what is meant or what is known is merely the cognitive experience itself, or something in it, then how can either knowledge or meaning be genuine?

In general there are three types of solution which have been offered. The first of these is representationalism, according to which the object never literally enters into the experience of the subject. This view recognizes, in at least one sense, the transcendence of the object known or meant; and thus avoids the reduction to absurdity which has been mentioned. The difficulty of this view is, of course, to reconcile such transcendence of the object with the possibility of knowing it. Second, there are identity-theories, both idealistic and realistic, according to which the object, or the object so *far* as it is known, is identical with some content of the subject's experience at the moment when the knowing takes place. The outstanding difficulty of this view is to avoid the reduction to absurdity, because it is incompatible with the supposition that anything can be known which lies beyond the immediate experience of the knower.[7] Such identity-theories are also liable to difficulty with the problem of error.

For the third type of theory – which includes both objective idealism and pragmatism – the object known is definable or specifiable in terms of experience, but the experience in terms of which the object is thus definable is not, exclusively, the experience of the subject at the moment of knowing; it transcends that experience. In rough general terms, objective idealism takes this relation between the experience in terms of which the object is specifiable and the experience which cognizes, to be the relation of something *deductively* implied to that in which it is implicit. That is, the present experience in which the knowing occurs – the idea or the given – is taken as determining implicitly the whole object in its reality, and as determining it unambiguously

[7] For an identity-theory of the realistic variety, the object known may transcend the knowing experience – because it is known only in part – but the object so far as it is genuinely cognized cannot.

and with certainty, if only we could be explicitly aware of all that is implied. In equally rough terms, pragmatism may be said to take this relation as *inductive*; the given experience of the moment of knowing is the basis of a probability-judgment concerning the experience (or experiences) which would verify, and in terms of which the real nature of the object is expressible.

It would probably be incorrect to take the logical positivists as holding an identity-theory of the cognitive relation.[8] But if they do not, then their conception of the object known, as constructed or 'constituted' in terms of given sense-data, requires to be interpreted so as to avoid an ambiguity which is possible. At this moment I am thinking of the wall behind my back. If I should turn around, I could verify my idea of it. But if at this moment I refer to the wall as a construction from presently given data, then the distinction between 'construction' as present concept, and 'construction' as that which this concept means to denote, is essential. Both are empirical data, if you like – but they are not the same data. The data which have their place in the concept are memories, visual and tactile images, anticipations; the data which would verify this conception would be perceptions. Not only are memories, ideas of imagination, and perceptions different events, but they are empirically distinguishable kinds of experience-content. Either, then, the wall which my idea denotes is merely the imagination-wall or recollection-wall, which is the immediate datum; or I cannot at this moment know the real wall which I mean; or – the third possibility – it is false that what I now know and mean by 'the wall' coincides with any complex of sense-data now in my mind.

It is on this point that the third type of theory is significant. For the pragmatic form of this third type knowing begins and ends in experience; but it does not end in the experience in which it begins. Hence the emphasis on the temporal nature of the knowing process, the leading character of ideas, and the function of knowledge as a guide to action. Knowing is a matter of two 'moments', the moment of assertion or entertainment and the moment of verification; both of these moments belonging to experience in the generic sense of that word. Knowledge will be true or correct only in so far as the present experience – of the entertainment of the meaning – envisages or anticipates correctly the experience or experiences which would verify it; that is, our knowledge is true if the anticipated experience is genuinely to be met with. But the entertaining experience can be truly cognitive, as against a mere

[8] There could be doubt; for example, Carnap says, "Between 'concepts' and 'objects' there is only a difference in the manner of speech" (*Logischer Aufbau der Welt*, Zusammenfassung, p. 262); and their conception of the relation between physical and mental might be taken to argue an identity-theory. But they have, I think, been principally absorbed in the problem of the *analysis* of the concept (or the object as an intellectual construction), and one should be chary of attempting to elicit from their writings any answer to the present question, which is of a quite different order. At least, I should not wish to presume to do so.

enjoyment of itself, only by the fact that what would be realized in the moment of verification is distinct from the experience which entertains or anticipates it. Otherwise error would be impossible – one cannot be mistaken about the immediate – and hence knowledge, as the opposite of error, would likewise be impossible. I do not mean to say, of course, that at the moment when something is believed or asserted it cannot have a ground in given experience, or be 'partially verified'; but it *is* meant that there must be something more, which is believed in or asserted, than what is verified immediately, if the experience is to have the significance of a knowing as contrasted with an esthetic enjoyment.

The same point can be phrased in another way by reference to the question whether, and in what sense, the datum, by means of which any item of reality is known, is distinct in its being from the cognoscendum.[9]

I should urge that any identity-theory which denies this difference between datum and cognoscendum is incompatible with the cognitive function of the idea or datum. This cognitive function is the guidance of behavior; and in order that the cognizing experience may perform this function there must be at least an element of anticipation or implicit prediction which foreshadows what is *not* here and now present in the datum.

For certain types of realism the problem thus set is taken to be that of the relation between data as items of experience and the reality in its independent existence, which is not any item or complex of items in experience. Pragmatism, in common with idealism and with logical positivism, repudiates the problem in this form as unreal.[10] For all three of these views the relation of datum to cognoscendum is taken to be a relation within experience (in the generic sense), or between one experience and others; not a relation between something in experience and something altogether out of it. The reasons for this attitude would be different in each case; but for all three views the principal ground of this repudiation is the obvious one that a relation of experience to what cannot be brought within experience is a relation which cannot be investigated, and one the very conception of which as cognitive involves a confusion of thought.

All three of these theories would agree that the cognoscendum must be defined, or constructed, or constituted for knowledge, in terms of experience. But if we are not to fall into the opposite error of the reduction to absurdity, which comes from identifying datum and cognoscendum, it must be recog-

[9] I borrow this formulation from the recent discussion of Strong and Lovejoy in the pages of *The Journal of Philosophy*, XXIX (1932) 673–687 and XXX (1933) 589–606.

[10] There may be doubt of this. I do not affirm it dogmatically; but this seems to express the intent of Dewey's denial of "antecedent reality," James's insistence that a thing is what is "known as," and Peirce's pronouncement that our concept of the effects of an object, which have practical bearings, exhausts our whole concept of the object.

nized that the experience of knowing and the experience in terms of which the object is specified cannot be simply identical.

The very simple point which is pertinent to the further issues of this paper is the fact that although knowledge is subject to the here-and-now predicament – the data must be immediate – it is essential to the cognitive function of the present experience that its cognoscendum should *not* be merely here and now. If, for example, there can be knowledge of a future event in one's own life, then the datum which is the vehicle of this anticipation is not the anticipated cognoscendum. And in so far as all empirical knowing has the dimension of anticipation or implicit prediction, the thing known is not to be identified with, or phrased exclusively in terms of, here-and-now experience. What is known now, *now* has the status of being verifiable; but in the nature of the case it does not and cannot have the status of being verifiable-now.[11] The only thing which is literally and completely verifiable-now is that which is immediate and now-verified.

This account is, of course, hopelessly inadequate, and raises all sorts of questions which cannot be dealt with here. But the points which are directly pertinent to the further discussion are these. (1) The conception that "empirical knowledge is confined to what we actually observe" is false. To know (empirically) is to be able to anticipate correctly further possible experience. If this is not the whole significance of such knowing, at least it is an essential part of it. (2) What is anticipated, known, or meant must indeed be something envisaged in terms of experience – the requirement of empirical meaning stands. But equally it is essential that what is empirically known or meant should *not* be something which is immediately and exhaustively verified, in what I have called the moment of entertainment.

It will also be of importance to consider a little the sense, or senses, of the word 'verifiable'. Like any word ending in 'able', this connotes possibility and hence connotes conditions under which this possibility is supposed to obtain. To advance the dictum that what is empirically known, and what is meant, must be verifiable, and omit all examination of the wide range of significance which could attach to 'possible verification', would be to leave the whole conception rather obscure. But instead of attempting here some pat formulation *a priori*, let us briefly survey different modes of the 'possibility' of the verifying experiences projected by meaningful assertions.

At this moment I have a visual presentation which leads me to assert that my watch lies before me on the table. If what I assert is true, then I could touch the watch, pick it up, and I should then observe certain familiar details which are not discernible at this distance from my eye. This verifying experience is

[11] We use the expression "verifiable now" oftentimes in the sense of "verifiable at will." That means literally "verifiable the next moment if I choose to meet certain understood conditions."

not actual; I do not touch the watch. But nothing is lacking for it except my own initiative. At least I believe that to be the case; and this belief is coordinate with the degree of my felt assurance that the watch is real and is mine. This is, perhaps, the simplest case of verifiability – observability at will. All the conditions of the verifying experience are present except only my intent to make the verification.[12]

Next, let us consider the other side of the moon.[13] This is something believed in but never directly observed. The belief is an inference or interpretation based upon direct observation; the moon behaves like a solid object and must, therefore, have another side. But what is believed in must, in order to be real, possess characters which are left undetermined in our belief about it. For instance, there must be mountains there; or there must be none. To speak more precisely, our belief includes alternatives which are not determined; but, if the thing believed in is what it is believed to be, these alternatives must be *determined in the object*. If there were nothing more, and more specific, to the other side of the moon than what is specifically determined in our construction of it, then it would be a logical abstraction instead of a physical reality. These undetermined characters are what we should see if we could build an X-ray telescope, or what we should find about us if we could construct a space-ship to fly up there and land. What we should observe if these things could be accomplished is what we mean by the other side of the moon as a physically real thing – as something more than a logical construction put upon presently given data.

The projected verification in this case is ideal in a sense which goes quite beyond the preceding example. It is humanly possible, perhaps; men may some day build space-ships or X-ray telescopes. But the conditions of this verification – or any other direct empirical verification of the thing in question – include some which we cannot meet at will. We cannot, by any chain of planned activity, completely bridge the gap between actual conditions and the projected verification. Obviously, then, unless belief in the other side of the moon is meaningless, it is not requisite to such empirical meaning that the verifying experience should even be possible at present, in any narrow interpretation of that word 'possible'. To analyse the conception of 'verifiable'

[12] Such a single experience would not be a theoretically complete verification of my assertion about the watch. As I have elsewhere indicated, no verification of the kind of knowledge commonly stated in propositions is ever absolutely complete and final. However, an *expected experience* of the watch can be completely verified – or falsified.

[13] It will be obvious that there are modes of verifiability which would fall between the preceding illustration and this one. For example, the verifying experience might be such as could be reached, from actual present conditions, by a more or less complicated chain of circumstances, but a chain every link of which is supposedly related to the preceding one in the manner of the first example.

which would extend to such cases would be a large order. I shall only suggest what I think might be some of the critical points. (1) As this example serves to illustrate, any reality must, in order to satisfy our empirical concept of it, transcend the concept itself. A construction imposed upon given data cannot be identical with a real object; the thing itself must be more specific, and in comparison with it the construction remains abstract. In making any verification we expect something which we cannot anticipate. This is a paradox in language; but it is, or should be, a commonplace of the distinction between ideas and objects. (2) In making 'verifiability' a criterion of empirical meaningfulness, the primary reference is to a supposed character of what is conceived rather than to any supposed approximation of the conditions of verification to the actual. (3) The requirement of 'verifiability' for *knowledge* is a stricter one, because knowing requires, in addition to meaningfulness, some ground of the assurance of truth. But, as this example makes clear, even the 'possible verification' which is requisite to empirical knowing cannot be confined to the practicalities, or by detailed comprehension of the procedure of such verification. We do not command the means for making any direct verification of our belief in the other side of the moon; but what this signifies is that, with all the means in the world, we do not *know how* to. If it be said that it is required for empirical meaning – or even for knowledge – that we should lay down a rule of operation for the process of verification, it should be observed that sometimes this rule of operation will have to be rather sketchy. This difficulty – if it is a difficulty – will be found to affect not only such extreme cases as the other side of the moon but quite commonplace items of knowledge as well.

I join with you in feeling that such considerations smack of triviality; but certainly a theory which could be overturned by such trivial facts would not be worth holding. Just what we can sensibly mean by 'empirically verifiable' is really a bit obscure. Perhaps the chief requirement ought to be that we should be able to analyse the supposed connection between the projected verifying experience and what is actually given (the 'rule of operation') in such wise that this procedure of verification can be envisaged *in analogy with* operations which can actually be carried out. The degree to which such analogy could be made complete would, I think, justly affect the significance of our supposed knowledge.

As a third example let us take the case of the electron. The existence of electrons is inferred from the behavior of oil-droplets between charged plates, tracks registered on photographs of the discharge from cathodes, and other such actually observed phenomena. But what is it that is inferred; or is anything really inferred? Some physicists, for example Bridgman, would say that our concept of the electron comprehends nothing more than these observable phenomena, systematically connected by mathematical equations in verifiable ways. The layman, however, and probably most physicists,

would not be satisfied to think of "electron" as merely a name for such observable phenomena. But what more may they suppose themselves to be believing in? An electron is too small to be seen through any microscope which ever can be made, and it would not stay put if a beam of light were directed upon it. It is equally beyond the reach of the other senses. But is the phrase "too small to be directly perceived" meaningful or is it not? And how direct must a "direct verification" be? Suppose it to be urged that no one can set a limit to scientific inventiveness, or anticipate the surprises which investigation of the subatomic will quite surely present; and that if or when such developments take place, definitely localized phenomena may perhaps be observed within the space to which the mass of the electron is assigned.

Whether this is or is not a question about the real nature of the electron, and what limitations should be imposed on useful conceptions in physics, are matters concerning which I could not have a competent opinion. But there is a general point here which all of us can judge. A hypothetical conception of an empirical reality cannot be definitely ruled out unless we can say categorically that the conditions of its verification could never be realized. Between those conceptions for the verification of which we can definitely specify a rule of operation, and those which we can definitely eliminate as theoretically impossible, there is an enormous gap. And any conception which falls in this middle ground is an hypothesis about empirical reality which possesses at least some degree of meaningfulness. If those who believe in the electron as a sort of ultramicroscopic bullet cannot envisage this object of their belief in such wise that they would be able to recognize certain empirical eventualities as the verification of it, in case the conditions of such verification *could* be met, then they deceive themselves and are talking nonsense. But if they can thus envisage what they believe in, then the fact that such verifying experience is highly improbable, and even that the detail of it must be left somewhat indefinite, is no bar to its meaningfulness. Any other decision would be a doctrinaire attempt to erect our ignorance as a limitation of reality.

The requirement of empirical meaning is at bottom nothing more than the obvious one that the terms we use should possess denotation. As this requirement is interpreted by pragmatists and positivists and others who share the tendencies of thought which have been mentioned, no concept has any denotation at all unless eventually in terms of sensuous data or imagery. It is only in such terms that a thing meant, or what a proposition asserts, could be recognized if presented to us. But, as the preceding considerations are intended to make clear, the envisagement of what would thus exhibit the denotation or verify the assertion – which is all that meaning requires – has little or nothing to do with the question whether the conditions under which the requisite presentations could be realized can be met or not. Whether such verfying experience is mine or is yours or is nobody's; whether it happens now or in the future or never; whether it is practically possible or humanly

problematic or clearly beyond our capacity to bring about – all this is beside the point when the only question is that of theoretical meaningfulness.

One may be tempted, in protest against various forms of transcendentalism and verbalism, to announce the unqualified dictum that only what is verifiable can be known, and only what is knowable can be the subject of a meaningful hypothesis. But such flat statement, while true in general, may nevertheless be misleading on account of an ambiguity in the word 'verifiable'. On the one hand this connotes a certain character of the content of one's assertion or hypothesis. This must be envisaged in sensuous terms; it must be the case that we could recognize certain empirical eventualities as verifying it, supposing that the conditions of such verifying experience could be satisfied. Verifiability in this sense requires an empirical *content* of the hypothesis, but has nothing to do with the practical or even the theoretical difficulties of verification. Whatever further restrictions may be appropriate in physics or any other natural science, the only general requirement of empirical meaning – which alone is pertinent to those hypotheses about reality which philosophy must consider – is this limitation to what can be expressed in terms which genuinely possess denotation.

On the other hand, 'verifiable' connotes the possibility of actually satisfying the conditions of verification. Or, to put it otherwise, verifiability may be taken to require 'possible experience' *as conditioned by the actual*; we must be able to find our way, step by step, from where we actually stand to this verifying experience. Hence practical or theoretical difficulties are limitations of verifiability in this second sense. These limitations may be genuinely pertinent to knowledge, because *knowledge* requires the *assurance of truth*; and whatever would prevent actual verification may prevent such assurance. But verifiability in this second sense has no relevance to meaning, because the assurance of truth is, obviously, not a condition of meaningfulness.

It is of importance to avoid confusing these two senses of 'verifiable' in assessing the significance of those considerations which methodological solipsism makes prominent. If it could be said that actual knowing must rest upon verification which, in the end, must be first-person and must be here and now when the knowing occurs, at least it would be an absurdity to translate this into the negation of meaning to whatever cannot be expressed in terms of first-person experience and of experience here and now. I impute this absurdity to no one; I would merely urge the necessity of avoiding it.

It is likewise important, in the same connection, to bear in mind what have been called the two moments of cognition. It is a fact that past experience is a given datum only in the form of memory; the future, only in the form of imagination. And the reports of others are data for the knower only in that form in which they lie within the egocentric predicament. Hence any idea which can occur with cognitive significance must be a construction by the knower, ultimately in terms of first-person present data. These predicaments,

however, are limitations of the moment of entertainment. If one should conclude that because the cognizing experience must take place within the boundaries of the first-person and the immediate, therefore the object of that knowledge, so far as it is genuinely known or meant, must also lie within those limits, one would be overlooking the distinction between the experience which entertains and the projected experience which would verify what is thus entertained. The distinction of these two is of the essence of cognition as contrasted with esthetic enjoyment of the immediate. To identify them would be to reduce knowledge and meaning to absurdity. Again, I do not impute to anyone this identification of the idea, in terms of immediate data, with the object, specifiable in terms of possible experience or experience which is anticipated. I would only urge the desirability of avoiding this fallacy.

In the time which remains it is a bit absurd even to suggest any bearings which the above may be supposed to have upon metaphysical problems. But with your indulgence I shall barely mention three such issues.

One traditional problem of metaphysics is immortality. The hypothesis of immortality is unverifiable in an obvious sense. Yet it is an hypothesis about our own future experience. And our understanding of what would verify it has no lack of clarity. It may well be that, apart from a supposed connection with more exigent and mundane problems such as those of ethics, this hypothesis is not a fruitful topic of philosophic consideration. But if it be maintained that only what is scientifically verifiable has meaning, then this conception is a case in point. It could hardly be verified by science; and there is no observation or experiment which science could make, the negative result of which would disprove it. That consideration, however, has nothing to do with its meaningfulness as an hypothesis about reality. To deny that this conception has an empirical content would be as little justified as to deny empirical content to the belief that these hills will still be here when we are gone.

Next let us consider that question about the external world, supposedly at issue between idealists and realists. One suspects that the real animus of debate between these two parties is, and always has been, a concern with the question of an essential relationship between cosmic processes and human values; and that if, historically, idealists have sought to capture their conclusion on this point by arguments derived from a Berkeleyan or similar analysis of knowledge, at least such attempt has been abandoned in current discussion. So that this question about the external world, in any easily statable form, is probably not pertinent to present controversy. But there is one formulation which, if it is too naïve to be thus pertinent, at least poses an intelligible question about the nature of reality. Let us phrase this as a realistic hypothesis: If all minds should disappear from the universe, the stars would still go on in their courses.

This hypothesis is humanly unverifiable. That, however, is merely a predicament, which prevents assurance of truth but does not affect meaning.

We can only express or envisage this hypothesis by means of imagination, and hence in terms of what any mind like ours *would* experience if, contrary to hypothesis, any mind *should* be there. But we do not need to commit the Berkeleyan naïveté of arguing that it is impossible to imagine a tree on a desert island which nobody is thinking of – because we are thinking of it ourselves. It is entirely meaningful, for example, to think of those inventions which nobody has ever thought of, or those numbers which no one will ever count; we can even frame the concept of those concepts which no one will ever frame. Those who would deny this on logical grounds exhibit a sense for paradox of language which is stronger than their sense of fact. Furthermore, *imagination* is sufficient for empirical meaning, though it requires *perception* for verification. I can imagine that future time which I shall never perceive; and humans can meaningfully think of that future when humanity may have run its cosmic course and all consciousness will have disappeared. It may be that the hypothesis of a reality with no sentience to be affected by it is not a particularly significant issue; though the idealist might have an interest in it for the sake of the light which decision about it would throw upon the nature which reality has now. In any case, the fact that it is unverifiable has no bearing upon its meaningfulness. Whether this hypothesis is true, is a genuine question about the nature of reality.

Finally, we may turn to the conception of other selves. The importance which this topic has for ethics will be obvious. Descartes conceived that the lower animals are a kind of automata; and the monstrous supposition that other humans are merely robots would have meaning if there should ever be a consistent solipsist to make it. The logical positivist does not deny that other humans have feelings; he circumvents the issue by a behavioristic interpretation of "having feelings." He points out that your toothache is a verifiable object of my knowledge; it is a construction put upon certain empirical items which are data for me – your tooth and your behavior. My own toothache is equally a construction. Until there are such prior constructions as the physical concept "teeth," from given sense-data, neither your toothache nor mine is a possible object of knowledge. And, similarly, until there is a construction involving such prior constructions as human bodies, there is no own-self or yourself as particular objects of knowledge. As knowable things, myself and yourself are equally constructions; and though as constructed objects they are fundamentally different in kind, the constructions are coordinate. That experience which is the original datum of *all* such constructions is, in Carnap's phrase, "without a subject."[14] Nevertheless it has that quality or status, characteristic of all given experience, which is indicated by the adjective "first-person."

[14] See *Logischer Aufbau der Welt*, §65.

With the general manner of this account of our knowledge of ourselves and others I think we should agree. But it does not touch the point at issue. Suppose I fear that I may have a toothache tomorrow. I entertain a conception involving various constructions from present data; my body, teeth, etc. But my present experience, by which I know or anticipate this future toothache, is not an experience of an *ache*. There is here that difference which has been noted between the experience which entertains and the experience which would verify, to which it implicitly refers. A robot could have a toothache, in the sense of having a swollen jaw and exhibiting all the appropriate behavior; but there would be no pain connected with it. The question of metaphysical solipsism is the question whether there is any pain connected with your observed behavior indicating toothache. The logical positivist claims that this issue has no meaning, because there is no empirical content which could verify the non-solipsistic assertion – that is, no content unless, following his procedure, I identify your pain with observable items such as the behavior which exhibits it; in which case it is verifiable in the first person. To make this identification, however, is to beg precisely the point at issue.

Let us compare the two cases of your toothache now and my toothache tomorrow. I cannot verify your toothache, as distinct from your observable behavior, because of the egocentric predicament. But neither can I verify my own future toothache – because of the now-predicament. My tomorrow's pain, however, may genuinely be an object of knowledge for me now, because a pain may be cognized by an experience in which that pain is not a given ingredient. (The imagination of a pain may be painful; but it is not the pain anticipated. If it were, all future events which we anticipate would be happening already.) *Your* pain I can *never* verify. But when I assert that you are not an automaton, I can envisage what I mean – and what makes the difference between the truth and falsity of my assertion – because I can imagine your pain, as distinct from all I can literally experience of you, just as I can imagine my own future pain, as distinct from the experience in which I now imagine it.

In the nature of the case I cannot verify you as another center of experience distinct from myself. Any verification which I might suppose myself to make would violate the hypothesis by being first-person experience. But there is nothing to which I can give more explicit empirical content than the supposition of a consciousness like mine connected with a body like my own. Whether there is any such would be a terribly important question about reality if anybody entertained a doubt about the answer. Whether you are another mind or only a sleep-walking body is a question of fact. And it cannot be exorcized by definitions – by defining 'meaningful' so as to limit it to the verifiable, and 'verifiable' by reference to the egocentric predicament.

This conception of other selves as metaphysical ultimates exemplifies the philosophic importance which may attach to a supposition which is never-

theless unverifiable on account of the limitations of knowing. Though empirical meaning is requisite to theoretical significance – and that consideration is of first importance in guarding against verbal nonsense in philosophy – still the sense in which a supposition is meaningful often outruns that in which the assurance of truth, by verification, can genuinely be hoped for. In limiting cases like this last question it may even outrun the possibility of verification altogether.

MEANING AND ACTION

C. I. Lewis. "Meaning and Action." *Journal of Philosophy* 36.21 (12 October 1939): 572–576.

To say anything new and important about Dewey's logic would be, I suspect, beyond my powers. I shall not attempt it but, instead, wish to offer here brief comment on one conception of his, which I take to be central for his logic and for his point of view in general, and which I believe to be both correct and important: the conception, namely, that meaning and action are essentially connected.

Dewey does not write by the method of theorem and corollary; and one does not find any single statement into which the full significance of this thesis has been compressed and from which all its implications can be drawn. But what is here in question is no platitude, to the effect that since humans are active beings their meanings are likely to reflect their interests and their practice. Nor does it merely serve to point an emphasis, characteristic of the theory in which it appears but setting it in opposition to no other which could plausibly be maintained. Rather, it is the distinctive conception, incompatible with most views, that the cognitive or meaning situation does not admit of bifurcation into an activity of the knower and a preformed object which is contemplated; that knowing or meaning is integral with other activities which shape the objects to which they are addressed; that meanings themselves serve to frame the situations of action into which they enter, and exercise an operational force upon what they serve to formulate. It is implied that an idea or a meaning, apart from some possible action and the reality in which it should eventuate, is a fictitious entity not found in human thinking. And conversely, it is implied that the objects of knowledge, without reference to meanings and the actions to which they may lead, are equally fictitious. From this conception there issues a sharp challenge to those views – comprising the greater number – which would portray the reality known as "antecedent" to the activity of knowing, and to "spectator" theories of knowledge which would represent the knower as a disinterested contemplator of a ready-made world which *qua* knower he does not affect.

So far from being a commonplace, this thesis, when fully grasped, has something of the aspect of a hard saying. Almost it is as if Dewey had claimed that all meanings and all inquiry are subject to a kind of indeterminacy principle. Thought itself displaces or transforms that which it means or

inquires about: but if it thus affects the object concerned, how can inquiry disclose what it sets out to reveal? One can not suppose that this thesis has met with that acquiescence which the relative absence of discussion would suggest. Its force has been insufficiently felt. This conception has not been generally accepted by philosophic readers; but it has been answered mainly by neglect.

Yet however contrary to prevailing views, or even paradoxical, this conception may be, the considerations which would enforce it are fairly obvious. That thinking, meaning, knowing are other than – as Dewey claims – activities performed at need, is *prima facie* implausible. But if they are thus instigated, an effect of them upon that to which they are directed is implied. That the activity of the knower is itself a part of the world-process and a factor in determining its events could not easily be denied. But if it is such, then plainly the conception that objects of inquiry are merely given to a contemplative knower, must be fundamentally erroneous.

For example, empirical knowledge, on almost any view, will be admitted to have the aspect or the pervasive implication of prediction. Any report of empirical fact, and any generalization such as a law of natural science, leads either to categorical predictions of future events or to hypothetical predictions that such and such will take place under certain specifiable circumstances. And that the main if not the exclusive motive of science and empirical knowledge in general is found in the possibility of such predictions will be denied by no one. Yet if the world-process were that kind of antecedently determined enchainment of events which it is often supposed that science must take it to be, in order that such prediction may be possible and valid, then precisely in being thus predictable reality must be inaccessible to and unalterable by any activity of the knower. In that case, what boots it to know this completely inevitable futurity? It requires no initiative on our part – cognitive or of any other sort – to "avoid the impossible and cooperate with the inevitable."

Such considerations might perhaps meet with the reply that our aim in knowing what is predetermined lies in something else; that we wish to know whether it will rain, not in order to affect the weather, but in order to know whether to carry an umbrella. But if this way of meeting the difficulty – suggested by the common-sense answer in our trivial example – were to be taken as a satisfactory kind of analysis of situations in which knowledge and action are involved, it would lead to difficulties which are serious if not insuperable. Because it would seem to assume that there are two sorts of futurities; those which are predetermined for our inquiry and about which alone unconditional predictions can be made – "It will rain" – and those which are not thus antecedently determined – "I shall get wet" – which depend on what we do in the light of this knowledge. The former classes are inaccessible to our action; the latter are not cognitions of objective reality but matters of decision. By implication, the world-process must be viewed as

divisible into those events which are unconditionally predictable and about which we can do nothing, and those our activity can affect but which are not the objects of any cognitive inquiry. Fully carried out, this would lead to the conclusion that knowledge – or at least knowledge as having implications for the future – is exclusively of the inevitable; but that this knowledge is of practical value exclusively for its bearing on what is unpredictable.

The point is not so much that one who should elevate the attitude suggested to the status of philosophical analysis would stand in danger of violating his own systematic presuppositions – though that is a fact. It is not consistently possible to carry out such a double-aspect view of the world: to think of it as if one could, *qua* knower, view it as made up of predetermined and unbreakable chains of events, with one's self outside and looking on; and then, having through such passive receptivity acquired knowledge, could step out of one's contemplative rôle and take a hand in shaping the future thus predicted. One can not in this fashion place the subject, who both knows and acts and whose knowing is integral with and for the sake of his acting, both in and out of the process of events to which his knowing and his acting are addressed. But I say that this is hardly the point: probably that "universal determinism" sometimes supposed to be an essential presupposition of science is not something to be judged false or true but merely a pedantic fable; such that even if admitted in words it could find no application to any actual situation in which a human investigator has a real purpose in prosecuting an inquiry.

The more important point is one which concerns the meaning of our predictions themselves – and so far as empirical knowledge is implicitly predictive, the meaning of what we know in general. Such meaning can not exclude but must include the significance of the knower's activity. Because the validity of a genuinely cognitive meaning must be capable of verification. That a substantive meaning applies or does not apply, that a proposition is true or false, must be capable of test. And what tests are pertinent, must be implicit in the meanings themselves. Whoever speaks of *X* but does not know how it could be determined whether a presented thing is *X* or not, means nothing by his term: whoever asserts *P* but could not specify how the truth or falsity of *P* should be determined, makes no genuinely meaningful statement. So much of the pragmatic conception of meaning is quite generally accepted, and could not well be denied; though hairs may be split in the interpretation of it.

The meaning of a prediction, or of a cognition implying predictions, must be found in some future possible experience or experiences which would confirm its truth. *But there are no such verifying or confirming experiences which can be predicted without reference to the activity of the subject.* There are no future experiences which, concretely enough specified, are inevitable. There could be no experience of ours genuinely foreseeable but such that literally we could do nothing about it. In fact, precisely the point of foreseeing

what is called "inevitable" – and it is seldom the experience itself which is so called – is that at least we may blunt the poignant painfulness of what is anticipated, or sharpen and clarify its satisfying quality, by our foresight. And in the case of most predictable eventualities, we can do something more than merely to modify their character as experienced by going forward to meet them in an altered attitude.

Furthermore, there is no dichotomy between categorically predictable eventualities – "It will rain" – and hypothetical and avoidable ones – "I shall get wet." All verifications, all predictable confirming experiences belong in the second classification. The fact of rain is verifiable only by some manner of experiencing it; by getting wet, or by seeing it, or hearing it, or.... But we shall not get wet if we protect ourselves; and there would be some manner or another of avoiding any one of these verifying experiences. We might refuse altogether to put our statement to the test. Each such possible verification turns out, on examination, to be some eventuality which will accrue or not accrue according as we adopt or refuse to adopt some attitude or course of action. And beyond such future possible experiences which would verify it, "It will rain" means nothing. Put in general terms, the meaning of any "fixed" or "objective" fact which could be believed in or asserted has, as the final terms of its analysis, some set of hypothetical propositions, the hypotheses in which concern some mode of action. In this nature of our empirical meanings lie the connection between knowing and doing, and the explanation of the fact that knowledge of that reality which "is what it is independently of being known" has application to our practice.

There would not be space here for comment on the consequences of this point concerning meanings. And, obviously, my discussion has been inadequate to the point itself. It is the less necessary to elaborate these implications because so many of them have been made clear in Dewey's writings.

Section Four

Evaluations of Lewis on Pragmatism

MR. LEWIS'S THEORY OF MEANING

George Boas. "Mr. Lewis's Theory of Meaning." *Journal of Philosophy* 28.12 (4 June 1931): 314–325.

Recent discussions of the meaning of meaning derive largely from Peirce's famous essay called "How to Make Our Ideas Clear." This essay, which was written for popular consumption, is of course none too precise, but in general its students have found its central point in the following formula, "Consider what effects, which might conceivably have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of our conception of the object."

An examination of this formula and its application by Peirce will show that the difficulties of his theory spring from ambiguities and obscurities in the following terms.

(1) What sort of effects are practical effects?

a. Are they sensible effects, in the believer's experience or in all believers' experience or in some believers' experience?

b. Are they "useful" effects, in the sense of desired effects, or supposedly desirable effects? Are they effects upon the believer's behavior or someone else's behavior or all behavior? Are they effects upon other objects of conception? Are they *necessary* effects or accidental effects? Are they effects of the *conceiving* of the object or effects of the *object* if it exists?

(2) What is the object of our conception? Is it a "thing" or a fact? This comes down to the question of the possibility of having a conception of an entity in isolation, aside from a mental image. Should the term "conception" be used both for mental images (if there be any) of things and judgments about the interrelations of things in time and space? This question is not simply one of verbal usage, but involves the theoretical problem of whether so-called mental images and judgments are sufficiently alike in fact as to be called by the same name.

(3) This is, then, the third question. What are *conceptions* or, to use the word in the title of the essay, *ideas*? In order to answer this question, it is obviously not enough to take some privately constructed theory of ideas and try to apply Peirce's theory to them but it is necessary to find, if possible, something in what used to be called our thinking of which it makes sense to say that it has meaning and see whether Peirce's theory actually describes it or whether it leads to absurd consequences.

This list of three questions shows at least some ambiguity in Peirce's theory and there are still other questions that might be asked. Most of the literature on the subject since 1878 has been built up by assuming that one possible definition of the terms used by Peirce is the "right" one. Definitions are, of course, arbitrary in the last analysis, but we sometimes call the usual definition the "right" one and when there is general agreement upon a definition no harm is done. Still, words used in philosophic discourse are so notoriously vague and the things and facts they are supposed to name so slippery, that one finds it almost impossible to be sure he has correctly understood any proposition in this field. And by "correctly" we mean "in the sense the author meant it to be understood." The discussion of "meaning" in Mr. C. I. Lewis's *Mind and the World Order*, as one might expect from its author, is almost uniquely free from the vagueness of his predecessors in this field and consequently provides a contribution to the theory in general that is peculiarly valuable.

Mr. Lewis's theory is in the tradition of Peirce. Peirce's object was, of course, to induce people to stop talking about things which they could know nothing about, to stop pronouncing unverifiable propositions. His paragraph on the ethical importance of clear ideas reads like a page from Bacon. Mr. Lewis's whole book is an attempt to achieve the clarity and precision of which Peirce pleaded the cause and though he never grows lyrical about the social good of clarity, he is dominated by a desire for clarity as an end in itself.

We may as well say at the outset that although Mr. Lewis's terminology is preëminently univalent (*eindeutig*) there are occasional discrepancies between his theory of meaning and his use of the word. It is difficult at times to know whether it is not equivalent with "designation" (p. 52), "signification" (p. 53), "interpretation" (p. 55), "connotation" (p. 57), "intention" (p. 60), "denotation" (p. 60), and so on, but I doubt whether such difficulties are an effective bar to understanding the theory as a whole or are serious enough to deserve more than mention.

Mr. Lewis's theory of "conceptualistic pragmatism" makes a sharp distinction between two realms of knowledge, the realm of "experience" and the realm of "concepts." The distinction between these two realms is not very different from that of Kant, although their peculiar relationship is explained on what purports to be an entirely un-Kantian basis. The three theses which Mr. Lewis defends are presented to the reader in his preface. They are as follows:

(1) "*A priori* truth is definitive in nature and rises exclusively from the analysis of concepts."

(2) "While the delineation of concepts is *a priori*, the application of any particular concept to particular given experience is hypothetical; the choice of conceptual systems for such application is instrumental or pragmatic, and empirical truth is never more than probable."

(3) "That experience in general is such as to be capable of conceptual interpretation, requires no peculiar and metaphysical assumption about the conformity of experience to the mind or its categories: it could not conceivably be otherwise" (p. x).

The result of these theses, if proved, is that what Kant would have called the form of experience is *a priori* but its matter *a posteriori*. But while what we shall continue to call the mind may analyse forms and discuss their interrelations, the fitting of experience to them is always experimental, tentative, and practical. In Kant they fitted, for after all in Kant there were no objective relations and, strictly speaking, all that could be discovered was what matter fitted into the mind's forms. This is not accepted by Mr. Lewis, as I understand him, for nature consists for him, I believe, in both terms and relations; both can be discovered, but every discovery is guided by rules and criteria which are presupposed.

The preliminary advantage of this point of view is that although it deprives empirical knowledge of certainty, it frees mathematics and logic from uncertainty. The disadvantage is that in giving mathematics and logic certainty, it makes them tautological, and denies the possibility of synthetic *a priori* judgments.

The distinction of two cognitive realms, the empirical and the *a priori* comes down to a rejection by Mr. Lewis of esthesis as knowledge. For him knowledge must involve interpretation and hence a conceptual element. "There is no knowledge," he explicitly states, "merely by direct awareness (p. 37. Cf. p. 38f.). This insistence upon the difference between knowledge and the sensuously given is of such importance not only for an understanding of Mr. Lewis's theory but of the whole pragmatic movement, that it is worth dwelling upon here. That this distinction is believed important by Mr. Lewis is demonstrated by the space he gives it.

Knowledge, then, for Mr. Lewis is the conceptual interpretation of the sensuously given and that interpretation takes time. The temporal extension of the interpretative process is what makes the verification of knowledge incomplete and precludes truth by correspondence according to the traditional formulae. For unless ideas in the sense of sensuous content and ideas in the sense of implicit or possible (if not actual) assertions, are the same, there is correspondence only in the former case between ideas and their objects. Aside from the question of whether there are such entities – i.e., as sensuous content – it is certain that what meaning they might be expected to have is entirely different from that possessed by ideas in the second sense. The specific patch of color before me may be said to mean a red rose, but it would be just as simple to say that it *is* a red rose, unless I have already assumed the existence of an infraperceptual red rose of which it is the sensum. But even with that assumption of a dualism between sense-data and what they represent, the representation consists in the symbol's being simply the effect

of a non-given cause, if such language is permitted me. It is certainly not the same relation as that between a red flag and an auction or the name "George Washington" and the man.

It is because of a confusion between ideas as mental content and ideas as interpretations or hypothetical judgments, both of which involve an apparent dualism like that recognized by common sense between symbol and symbolized, that answers to the first question are held to be answers to the second. Thus it would seem to be believed by certain epistemological dualists that the occurrence of a mental content of even the simplest sensory sort, since it is what Mr. Lovejoy has called the vicarious presence of an object different from it, carries with it the information of the object of which it is the vicarious presence. It is precisely that which Mr. Lewis denies, since if the transcendent reference of such ideas – i.e., sense-data – could be read in the sense-data with no more ado than inspection, error would be as impossible as in epistemological monism and disputes about physical objects and the host of supposititious scientific objects would never arise.[1]

It is then only in the case of interpretation or judgment, when something is specifically asserted either about the sense-data or about other entities, that the question of truth or falsity and consequently the question of meaning enters. For the concept is defined by Mr. Lewis as a meaning. It is "that meaning which must be common to two minds when they understand each other by the use of a substantive or its equivalent" (p. 70). That there is such a community of meaning is admittedly an assumption (pp. 70, 72), for the only way in which it can be detected is by the reports of various minds and their subsequent acts. In so far as this meaning is carried by an idea in the sense of a sense-datum, there is no telling whether two people have the same idea – except by introspective reports, which may be unreliable. But that is of no more importance for a consideration of community of meaning than the fact that two symbols as unlike as *cheval* and *horse* may mean the same thing. So long as our definitions and their applications to the presented are alike, we can communicate with one another and share meanings. But how can *A* know that his definitions are the same as *B*'s and that he is applying them in the same way, when their esthetic data are private and ineffable? Mr. Lewis seems to recognize this difficulty for he says (p. 77) that no concept would have meaning "if we could not, through the terms in which that meaning is explicated, get back eventually to concepts which are correlated for us with specific and identifiable qualities of sense." That is, *cheval* and *horse* could not be known to mean the same thing unless the Frenchman and the Englishman correlated the symbols with what turns out to be the same

[1] This, of course, does not concern the dualism between present content and extrapolated unpresented content. See *The Revolt Against Dualism*, p. 268f.

sensible object.[2] It would seem to follow that if a term were correlated on no level of experience with any sensible object, real or imaginary, that it had no meaning.

The two explications of meanings – by definition and by behavior – are of different status. Definitions exhaust the denotations of the terms, but are confined to the realm of concepts (p. 79). Behavior is used almost exclusively in conveying the meaning of a word where the concept itself is already something shared (*Ib.*). This would seem to give us not merely two kinds of things which possess meaning, but two kinds of meaning, the kind of meaning words have and that which concepts have. But nevertheless there must be some priority between them, unless concepts and language are entirely disparate, which of course they are not.

Leaving the meaning of concepts aside – and concepts, be it noted are the relational element in experience – the meaning of words, which seems to correspond to the meaning of the "given," is what the given, sense-datum or percept, suggests of a "practical" nature (p. 49f.). In interpreting this meaning, two relations of the given are revealed, (*a*) that of the immediately presented to further actual or possible experience, and (*b*) its relation to my interest and action (p. 51). These both seem individualistic and one gathers that the meaning of the immediately presented is only social in so far as it accidentally happens to be so. For Mr. Lewis has said, "All that comes under this broad term 'meaning' (unless immediate value or the specificity of sense-quality should be included) is brought to this experience by the mind, as is evidenced by the fact that in this respect the experience is alterable to my interest and my will" (p. 51). Thus the sense-datum has in itself as so much color or sound or what not no meaning of any type, but acquires meaning through the use to which it is put. How grossly utilitarian such meaning may be is not indicated by Mr. Lewis, but that it must be tested by the "pragmatic test" of Peirce and James is admitted by him in an important footnote (p. 64f.).[3] But apparently no more is intended than that nouns indicate human purposes rather than human observations. "My designation of this thing as 'pen' reflects my purpose to write; as 'cylinder' my desire to explain a problem in geometry or mechanics; as 'a poor buy' my resolution to be more careful hereafter in my expenditures" (p. 52). At the same time if I refer to your pen as a pen, I do not necessarily do so with any purpose to write, though it is true that this word "pen," originally meaning a feather, has come to mean an instrument. But what has its instrumentality to do with its meaning? "If this is a pen, it can satisfy my purpose to write," is certainly not equivalent to, "If this satisfies my purpose to write, it is a pen." This seems like silly

[2] But, as we say, the privacy of sense-data makes this correlation theoretically impossible.

[3] See also (p. 34) the caution against interpreting pragmatism too biologically.

quibbling in this place, but apply it to the cylinder. "If this is a cylinder, it will help explain a problem in geometry"; "If this helps explain a problem in geometry, it is a cylinder." But though only a pen will fulfill a purpose to write in a certain way and only a cylinder will solve certain geometrical problems there is no more reason to make the utility equivalent to the meaning than to make the inherent formal properties of the objects named the basis of their utilities. The cylinder solves the problem because it is a cylinder and the pen writes because it is a pen. If only cylinders and pens fulfill the specific purposes in mind, then it obviously makes no difference whether the object or the purpose is stated as basic. For propositions noting the relation between object and purpose are like definitions and therefore simply convertible.

If, however, this be true, then meanings in behavior are just as analytic and *a priori* as meanings in conceptual thought. For it would either make nonsense to say, "If any writing instrument is a pen, then a pencil is a pen," or else it would be true. If it is nonsense, that is because formal properties are recognized – and not necessarily by use – in an instrument which makes it a suitable instrument, in which case the meaning of a term is not simply practical, but is indicative of observable characteristics which I have been calling "formal." Thus a cylinder has been defined as "the surface traced out by a line, named the generatrix, which moves parallel to itself and always passes through the circumference of a curve, named the directrix." One can see whether a thing is a cylinder or not by applying certain tests. And it is incontestable that if there were no way of telling whether things were cylindrical or not, there would be no sense in using the term. But at the same time the only purpose of mine its cylindricity as such could fulfill would be the purpose of applying the tests of cylindricity. It seems to the writer important to bear this in mind, for if all our contact with the world is purposeful then the word "purpose" has lost its selective and specific meaning.

Moreover, by bearing this in mind one may retain the benefits of the pragmatic technique and of operationalism without having to accept the peculiar metaphysics associated with it. I should admit that unverifiable truths and untestable meanings had best be omitted from all discussion. At the same time those who say that the proposition, "If sodium is burned, a yellow flame will be seen," is identical with the proposition, "Sodium is the sight of a yellow flame" seem to me to be talking nonsense. For one can not pretend that the sight of a yellow flame has the atomic weight of 23. Difficulties of this sort are numberless if this strict interpretation of operationalism is adhered to.

It is not entirely clear to what extent Mr. Lewis goes with his pragmatism. Though he maintains that there is a realm of *a priori* knowledge which can not be invalidated by experience, yet he agrees that "the ultimate criteria of the laws of logic are pragmatic" (p. 24). This is based upon the discovery that there is no basis within any logic for choosing it rather than another. Hence

the choice must be made on external grounds which "human bent and intellectual convenience" (p. 248) determine. That the purely *a priori* has such applicability, that it may serve human bent and intellectual convenience can surely be no accident. It is true that queer algebras and logics may be invented, but it is not true that they are equally convenient. Their convenience certainly is grounded upon their conformity to experience, as the specific utility of a pen is grounded in its specific makeup. This is admitted by Mr. Lewis when he speaks of definitions in the natural sciences (p. 257). "If definition is unsuccessful, as early scientific definitions mostly have been, it is because the classification thus set up corresponds with no *natural cleavage* and does not correlate with sufficiently important *uniformities of behavior*" (my italics). The natural cleavages would thus seem to be the basis of the utility of the definition. But Mr. Lewis no sooner stated this than he denies it. "The alchemist's definitions of the elements, for instance, are the clue to his indifferent success; the definitive properties pick out amorphous groups which have little significance of further uniformity. Not until such crucial properties as combining weights become the basis of classification is it possible to arrive at satisfactory laws of chemistry. *The earlier definitions can not be said to have been false; they were merely useless or insufficient to the purposes in hand* (p. 257f. My italics).

It is, of course, true that combining weights are determined by certain tests which chemists chose to make and hence are no more essential in the metaphysical sense than the older and more superficial definitory characters. But at the same time they do not constitute definitions which are arbitrary in the same sense that the definitions of "point," "line," and "plane" are arbitrary in geometry. For the constancy of combining weights is the one common property that all elements have; it is not merely assumed that they have it; and though few actual specimens in a chemical laboratory perfectly illustrate the law, they illustrate it to a very high degree. Its convenience is thus explicable and not final. It might have been much more convenient if elements would combine by volume rather than weight, but that consideration has never had much influence upon the elements.

There is no doubt that "the naming, classifying, defining activity is at each step prior to the investigation" (p. 259). It is also true that "we cannot even interrogate experience without a network of categories and definitive concepts.... We must first be in possession of criteria which tell us what experience would answer what questions, and how, before observation or experiment could tell us anything" (*Ib.*). All that is granted. But having our preliminary categories and definitive concepts, we set to work to apply them to nature. Sometimes they work; sometimes they do not work. When they do not, we are sure that they are wrong. When they do, we have a suspicion, but no certainty, that they are right. If we have no reason to suspect them, we retain them. If we find them contradicted, we reject them. That is actual scien-

tific practice, as we all know. And though the reasons for accepting a definition or category are pragmatic, those for rejecting one are not. If we have no impulse to apply our categories, then one set is obviously as good as another. But if one were to apply the test of Peirce and James to such categories, then until they were tested at least in imagination by experience they would not even have meaning.

Mr. Lewis seems to feel that the contradiction of the *a priori* by experience is no proof of its falsity (p. 264). We have admitted that its correlation is no proof of its truth. But the two situations are different, both theoretically and practically, and because we may choose to cling to old theories though they begin involved and cumbersome – such as the Ptolemaic system in the seventeenth century – is no reason to cling to them when what they imply is definitely disproved by a crucial experiment. Thus the phenomena described in the law of falling bodies may not be accurately explained by Newtonian physics, but merely consistent with it. But we know that if it be true, the Aristotelian physics is false. By a revision of Aristotelian physics we may be able to account for the phenomena as well as by Newtonian physics. But a revised theory is not a theory before revision. And though some men might still cling to the contradicted theory on the ground that all the contradictory experiments were sleight-of-hand tricks or magic, such a person would mean by tricks and magic what normal people mean by natural circumstances.

But even in the case of the most abstract categories – those of logic and geometry – in what sense are they prior to experience? It has been asserted, for instance, that though their genesis is in experience they can not be either validated or invalidated by any empirical situation. Thus "*p* is either true or false" is true regardless of whether *p* is actually true or false and in that sense of the word is prior to experience. At the same time both true and false propositions are found even in the crudest empirical judgments, recognized as such by people innocent of all logic.[4] The incompatibility between truth and falsity is again recognized empirically when even children catch each other lying. Were there a third logical value besides truth and falsity in experience, it is certainly highly doubtful whether "p is either true or false" would ever have been postulated. When meaningless propositions and propositional functions were recognized, qualifications to exclude them from the argument were made. It is, of course, true that one can invent a third value and work out a calculus of implication from a trivalent logic. And it is equally true that such a calculus would be logically prior to any implications made by its means. At the same time its very divagation from the bivalent logic we use would be evidence of its experiential origin, for just as one makes the generalization,

[4] Mr. Lewis recognizes this difficulty, but he avoids it by the theory of "unconscious meaning," or "meanings implicit in behavior" (p. 85). Whose meanings are they then? The "behavers" or the "behaviorists"?

"All crows are black" from observing crows, so we could assert, "Some crows are not black," in denial of the experiential generalization. It would, let us assume, not be true of experience, but that would not prevent its having an empirical origin.

If we do not grant human nature the power of abstracting, generalizing, contradicting, imaginatively combining, the tentative discoveries it makes in its dealings with the world, then to be sure the use of concepts and categories becomes a mystery. Mr. Lewis is perhaps too content to leave it a mystery. "The question," he says (p. 69f.)," how meaning *can* be objective and shared, when the psychological states which are bearers of this meaning are separate existences and not even identical in their qualitative content, is one of the important problems of meaning." And again, "That meanings may have this sort of objectivity is a fundamental assumption of science or of any other intellectual enterprise.... There must be meanings which are common to minds when they coöperate in scientific or even in merely practical endeavors. Otherwise the coöperation is illusory; and one cannot escape the question how such common meaning stands related to different minds or psychological states which mean" (p. 70).

Mr. Lewis (p. 71) rejects the Platonistic and neo-realistic answers to this question. He also refuses (p. 72) to resign the problem to the psychologist, since he too must begin by assuming the existence of common meanings like the rest of us. He admits (p. 91) that the possibility of common concepts is conditioned "first, by the fact that we are creatures fundamentally alike, having in the large the same needs and interests and powers of discrimination and relation; and second, that we are confronted by a common reality mediated to us in sense-experience which is comparable." In this passage and in the paragraph following, the coincidence of concepts seems to be based largely on coincidence of bodily reactions in the common reality, and not at all on a transcendental unity of apperception which earlier passages might suggest. But here a question of fact is raised. If our common ways of behaving are not necessarily mediated "by any direct psychological identity of experience" (p. 92), then how in the world would Richard Roe know that his ways of behaving are identical with those of John Doe? For it is perfectly possible for two people to behave alike without knowing it. Indeed John Doe has to be aware of his modes of behavior and of Richard Roe's and of their similarity and the same thing has to be true of Richard Roe. This also seems to be admitted by Mr. Lewis (p. 103), but with no sense of its importance, when he says, "I correctly attribute a certain purpose, like mine, to another if I observe that he performs an act like mine and suppose correctly[5] that it

[5] The word "correctly," of course, presents the whole problem. How could one test its meaning in this case?

is the result of an intention involving the same congruence between anticipation and result which I find in my own case." But he denies, and perhaps rightly, that one need suppose that "either purposes in general or the content of this act in particular are, as items of immediate experience, identical in his case and in mine, in order to 'understand his purposes'" (p. 103). But if one is not to have identity of immediate experience – and it is hard to see how one could have on Mr. Lewis's theory – one has simply identity of meaning and that is an end of it. But that discovery is not a solution of the problem of common meaning.

My point here is that identity of behavior – as so much matter in motion – could never convey identity of meaning, otherwise a wheel on one end of an axle might be said to have a knowledge of its identity of purpose with the wheel on the other end. Mr. Lewis's point is that speech is a form of behavior and apparently that what one form of behavior can do another can.[6] But it is precisely by the fact that language conveys meanings that it is differentiated from other forms of behavior. But to note that is to note the primacy and mystery of meaning, and not to give a theory of it. It may well be agreed that language would be meaningless if its terms could not be correlated with certain bodily movements, for bodily movements are the only way we have of expressing our thoughts. To avoid psychophysical dualism one may say that these thoughts are molecular movements, if one wish, but the fact remains that they have a characteristic which differentiates them from all other movements and which therefore erects a barrier around them and delimits them as a special class. Whereupon your dualism is as good as back again. For what makes these movements of interest to philosophy and psychology is not what they have in common with other movements, but what they do not have in common.

There are then according to Mr. Lewis two kinds of meaning corresponding to esthesis and knowledge, i.e., "the direct non-sharable meaning of reference to some complex of sense-qualities," and "the logical, sharable meaning of further conceptual relations." His theory is largely a polemic, and a justified one in the opinion of the writer of this paper, against founding the one kind of meaning upon the other. He further distinguishes two aspects of logical meaning, (a) its apriority, (b) its intersubjectivity. Its apriority is evidenced by what amounts to man's ability to handle propositional functions; its intersubjectivity is evidenced by the identity between various individuals' behavior including the use of language. But though propositional functions assert nothing about nature, nevertheless the relations symbolized in them are duplicates of, or generalizations from, or contradictions of relations met with in our daily life. Otherwise no implications could be drawn from them whatsoever. We could deduce from the propositional function "$x > y$," the

[6] For the identity of speech and behavior, see esp. pp. 109ff, 84, 87, 102.

conclusion that "$y < x$." "But we could deduce nothing from the propositional function "x O y" until we know what is popularly called the "meaning" of O. Nor, as psychologists pointed out hundreds of years ago, could we give O a meaning which had no similarity to or definable difference from some experienced type of relation.[7]

As for intersubjectivity, it is true that we should have no ideas of or symbols for common meanings if there were no common behavior. Similarly there is not much point in discussing theories which have no applicability to behavior, for there would be no telling whether they were true or false and hence they would be meaningless. But it is needless to point out to a logician, least of all to Mr. Lewis, that "p implies q" does not necessarily assert p of the natural world. It may be said that the system which is applicable is no different formally from the queer systems. That may be granted. But in that case its meaning is nil as far as human behavior is concerned. If its meaning is acquired, however, from abstraction of common properties, then it can not be *a priori* except in the sense that a child is logically prior to a parent. In other words one first derives it from experience, organizes it, makes it conform to experience and then calls it logically prior to experience. How does it differ from the *a posteriori*? Only in the degree of analysis and organization. This I recognize as a naïve and perhaps vulgar comment. But philosophy at certain stages of its history has benefited rather than suffered from contact with naïveté and vulgar sense.

If we now turn back to Mr. Lewis's three theses we find that first *a priori* truth is definitive in nature and rises exclusively from the analysis of concepts. But since concepts are uniform ways of behavior, *a priori* truth arises exclusively from our ways of behavior. But what guides us in our analysis we are not told. We find, second, that the application of any particular concept to a particular given experience is hypothetical. But if it is an abstraction of what experience has in common with other experiences, its application ought to be assured in advance and empirical truth as certain as any other, if we apply the right system of concepts. We find, third, that the fact that experience in general is such as to be capable of conceptual interpretation requires no peculiar and metaphysical assumption about the conformity of experience to the mind or its categories; it could not conceivably be otherwise. This is irrefutable if conceptual interpretation is an abstraction of observed uniformities of behavior or experience; for then experience conforms to the mind since the mind conforms to experience. But if that be true, then the "*a priori*" is simply a name for highly analyzed and systematized empirical generalizations. It is too perfect to apply rigidly to experience, but that turns out to be of no moment. Why does it need a special name?

[7] Of course these remarks are stupid if man can not think.

MR. LEWIS AND THE *A PRIORI*

Arthur E. Murphy. "Mr. Lewis and the *A Priori*." *Journal of Philosophy* 29.7 (31 March 1932): 169–181.

It is my purpose in this paper to criticize and, so far as may be, to disprove a theory about the nature of knowledge, and of *a priori* knowledge concerning physical reality in particular, which appears to be one that Mr. Lewis defends in *Mind and the World Order*. I say "appears" advisedly, since it is quite plain that he does not always maintain it; indeed, as I shall later try to show, he provides us in this same book with all the materials necessary for its refutation. And some of my colleagues have argued that he never "really" holds it at all, but only seems to do so through the use of a terminology whose associations are, to say the least, misleading.

Whether or not this is in fact the case I am quite unable to say. At any rate, the view in question is widely current among us, and has gained considerable aid and comfort from a not implausible interpretation of Mr. Lewis's statements about the *a priori*. To isolate this to my mind objectionable view, and to show that it is flagrantly inconsistent not only with sound doctrine on the subject, but with the excellently sound doctrine which Mr. Lewis himself lays down elsewhere in this same book, may serve in a measure to clarify this important problem.

The theory in question I will call the "dialectical" theory of truth, or the theory of truth as dialectical. And I shall limit myself to a discussion of the rôle of such dialectical truth in our knowledge of the external world – what Kant would have called the phenomenal world – as contrasted with pure experience on the one hand and with pure concepts on the other. According to this "dialectical" theory, the truth about the external world, such truth for example as physics claims to afford, is determined in part by the interpretative attitude of "the mind." In its simplest form this seems to mean (*a*) that the truth about physical objects depends on what we mean by them – on the way in which we "freely" interpret the data of experience, (*b*) that this interpretation is addressed merely to ourselves and hence needs no external support, and (*c*) that it can be maintained *as knowledge of physical reality* no matter what experience may be, not because it is able to delimit experience in advance, but precisely because it does not claim to do so. Being equally compatible with any empirical alternative, it can be held no matter what the subsequent course of events may reveal. This amounts to saying that there is a truth about physical reality which depends

simply upon the way we interpret it, and that in respect of this truth – though, of course, of no other – the mind legislates for reality. This is the view that I shall criticize, and it is one that Mr. Lewis appears sometimes to defend. Since in fairness to its defenders we should see it at its best, I propose to let it speak in terms of those aspects of his theory which seem to support it.

The basis for the view is found in a situation with which Mr. Lewis deals at length. The truth or falsity of a judgment is plainly indeterminate apart from a specification of its objective, of what it is about. And recent doctrines about the relativity of knowledge in various fields have brought us to see that it is not as easy as men had previously supposed to know what one is talking about. The term "reality," for example, has "a curious complexity." For "the adjective 'real' is systematically ambiguous and can have a single meaning only in a special sense. The ascription of reality to the content of any particular experience is always elliptical: some qualification – material reality, psychic reality, mathematical reality, is always understood. And whatever is real in one such sense will be unreal in others. Conversely, every given content of experience is a reality of one sort or other; so that the problem of distinguishing real from unreal, the principles of which metaphysics seeks to formulate, is always a problem of right understanding, of referring the given experience to its proper category" (page 11).[1]

I have quoted this passage at length because I think it crucial for much that is to follow. So long as one believes, as some of our contemporaries still do, that there is just *one* "right" meaning for reality the question as to what we are talking about in judgments about reality does not arise. We *must* be talking about the Absolute, or the feeling of feelings, or the motion of electrons, even when we *seem* to have something quite different in mind. Once realized, however, that the term requires further specification, and it becomes evident that *apart from such specification* the truth is simply indeterminate. Is "finite mind" real? Is it real in what sense? *It all depends on what you mean by "real,"* on how you interpret this term. And this interpretation, clearly, is the work of the mind.

Evidently the recognition of plural reference, of systematic ambiguity in the categories of thought apart from some further context of relatedness, does raise the problem of meaning, of interpretation, in a unique form. And since I wholly agree with Mr. Lewis in the belief that most descriptive terms, from "length" to "reality," do possess such systematic ambiguity in their ordinary philosophical usage, I welcome the inquiry into the implications of the specification of meanings which it seems so urgently to require.

There is, then, a sense in which whether a judgment is *true* depends upon what the judgment *is* – i.e., on what it means. Is a given object three feet long?

[1] All page references are to *Mind and the World Order*, New York, 1929. All italics in quotations are in the text itself.

It depends on what you mean by "three feet," and because no one measure-system is in itself *the* correct one, it follows that "the mind" must choose between these various meanings in order to specify a determinate object of judgment. Apart from such choice of reference the judgment that "this object is three feet long" is neither true nor false, but simply indefinite. This is the point of departure for theories that take relativity seriously in their account of knowledge. We shall return to it in the sequel.

We are now to apply this general analysis to the status of "the datum" in knowledge. There is a brute fact element in experience, something not merely given but coercively given, which so far as it goes is authoritative in knowledge as nothing else can be. Mr. Lewis is emphatic on this point. But it is equally the case that this "given" is not in itself completely coercive in most of our judgments about the natural world, i.e., whenever we are judging about the sort of reality that is more than mere qualitative content. Being as such equally compatible with different hypotheses about physical objects, it does not force us to accept any one alternative rather than another. It follows that so far as the datum goes the mind is in a measure "free" in its interpretations of any objects other than data, to which it may refer. An interpretation which might have been different for exactly the same given experience is made on some other ground than mere givenness; it is "freely" taken, and, if we divide knowledge into the datum and the work of the mind, falls in the latter rather than in the former division.

This at times seems to be precisely Mr. Lewis's view of the matter. For "The two elements to be distinguished in knowledge are the concept, which is the product of the activity of the thought, and the sensuously given, which is independent of such activity" (p. 37). The datum is that to which thought must conform since "If there were no datum given to the mind then knowledge must be contentless and arbitrary; there would be nothing which it must be true to" (p. 39); and in matters of interpretation the mind is not wholly determined by the datum: "In such problems (of interpretation) the mind finds itself uncompelled save by its own purposes and needs. What is fixed datum and must be conformed to is only that welter of the given in which not even the distinction between real and unreal has yet been made. The rest is completely and exclusively our problem of interpretation" (p. 265).

Now what about this interpretation itself? That it transcends the given we have seen. But it refers, nominally at least, to a reality other than the given, which it pretends to qualify. Is it not objectively determined, so far as it claims to be true, by its relation to this further object? Can we explain the truth of judgments about physical objects by referring to the fact that "the datum" does not fully specify their nature, and that, as a consequence, we are not completely determined by *it* in our judgment *of them*?

Mr. Lewis answers with the following decisive statement. "That only can be a priori which is true *no matter what.* What is anticipated is not the given

but our attitude toward it; it formulates an uncompelled initiative of mind, our categorical ways of acting. Truth which is a priori anticipates the character of the *real*: otherwise it would possess no significance whatever. The real, however, is not the given as such, but the given categorically interpreted. In determining its own interpretations – and only so – the mind legislates for reality no matter what future experience may bring" (p. 197).

The truth about our interpretations is free and can be determined in advance of experience. It is, hence, "*a priori*," because it is addressed to ourselves, not to subsequent experience. Thus "Knowledge of such a priori principles requires only reflective self-consciousness, because it is simply knowledge of those criteria which we apply in classifying experience in one or another fashion, interpreting it in one or another way. A categorical interpretation ... does not preclude any imaginable or unimaginable content of experience in the future, but only precludes our interpreting it in a fashion contrary to our predetermined attitude or bent" (pp. 227–228). It is obvious, consequently, that "definition, classification and inference represent no operation in the world of things, but only our categorical attitudes of mind" (p. 247). And finally, "The a priori does not dictate to nature but concerns our interpretation of empirical facts" (pp. 304).

The position, so far, seems straightforward. The truth of an interpretation can be independent of the datum because it is not about the datum. It can be independent of the future course of experience because it makes no statement about that experience. Nor does it "dictate to nature," but is simply addressed to ourselves. So far so good.

Yet the *a priori* is supposed to provide us some knowledge about physical reality. As Mr. Lewis is later to argue, it is because we can be certain *a priori* of some such principles that in our study of physical reality we have "a basal minimum of law." How can the mind thus legislate for reality by means of commands addressed *to itself*? This is the paradox that still requires explanation. The answer is that our legislation is merely definitive, explicative, it concerns the meanings we put upon experience, and meanings are preëminently "of the mind." To say that "all men are mortal," if it is taken as explicating the *meaning* of the term "man," does not legislate out of existence any possible reality since an immortal man is by definition not possible. And that definition is of our own making. "Not only is the meaning assigned to words more or less a matter of choice – that consideration is relatively trivial, – but the manner in which the precise classifications which definition embodies shall be affected, is something not dictated by experience. If experience were other than it is, the definition and its corresponding classification might be inconvenient, useless or fantastic, but it could not be false. Mind makes classifications and determines meanings; in so doing it creates that truth without which there could be no other truth" (p. 240).

This statement confers really surprising privileges upon a definition. On the one hand, as a mere definition, it "cannot be false"; on the other, equally as a definition, it "creates truth." How both of these assertions can be true at once is a further question; but that they must both be true, that a definition is *at once* merely addressed to ourselves, as a way in which *we* classify things, *and also* legislates for the things in question, is the curious conclusion to which we are driven.

The justification for it is discovered not in a new analysis of *reality*, but only in a renewed reference to the indeterminate character of given experience. We can maintain these definitive laws as legislation for reality, because given experience can never disprove them. "The a priori as thus definitive or explicative, representing principles of order and criteria of reality ... is a truth about our own interpretative attitude ... imposes no limitation upon the future possibilities of experience" (p. 231). And this because "The proposition that is a priori does *not* assert any limitation of experience; it only asserts that whatever lacks some essential property, *X*, is not to be classified under some concept, *A*" (p. 303).

The legislation of mind is "free," moreover, in this final sense that it "has alternatives," and this is the very mark and sign of its dominion. "What is a priori does not compel the mind's acceptance. It is the given experience, the brute-fact element in knowledge, which the mind must accept willy-nilly. The a priori represents the activity of mind itself; it represents an attitude in some sense freely taken. That we elicit some formula as a principle means that we take it as forbidding something ... which in some sense has significance. That which is incapable of any alternative is utterly devoid of meaning. The necessity of the *a priori* is its character as legislative act. It represents a constraint imposed by the mind, not a constraint imposed upon the mind by something else" (pp. 196–197). And, most conclusively, "the a priori principle which is definitive, and not a material truth of the content of experience, *has alternatives*" (p. 232).

We have now before us a complete conspectus of this dialectical theory of truth. The mind legislates for reality because there is a kind of truth about the external world which is at *once* a matter of definition, neither true nor false, *and also* prescribes the nature of the objects that are to exemplify it. This truth can be maintained independently of experience because an experience could only refute it in case it provided a relevant instance; while the decision as to whether or not it is a relevant instance is itself a mental interpretation, a choice freely made. And this choice is properly called legislative because there were possible alternatives which the mind might have adopted instead; it is the result of our active initiative.

And as we have seen there are passages in *Mind and the World Order* which seem to support this theory. I maintain that it is invalid from beginning to end. I should hesitate to make such an assertion on my own authority; fortunately

that is not necessary. Mr. Lewis has himself contradicted its principal theses definitely and in detail, and it is to the weight of his judgment that I shall appeal throughout, in attempting to show (1) that "the mind" is not "free" or legislative with respect to the truth of any judgment about objects; (2) that the "interpretative principles" of mind, so far as they claim to be about physical reality at all, are not simply addressed to ourselves and hence their truth is *not* "created by mind"; and finally (3) that all given experience falls under one category or another quite independently of how we interpret it, that in so far as it is thus categorized it is limited by a generalization that refers to it, and that to the assumption that this limitation exists there is, on Mr. Lewis's own showing, no alternative whatever.

1. It is true that in its judgments about physical reality the mind is uncompelled by the datum *as such*. But that is simply because in all such cases the datum as such is not the object about which it is judging. The minimum object of knowledge, so far as Mr. Lewis is concerned, is the datum – or quale – in determinate relationships to other actual or possible experiences. "What is essential for understanding and for communication is not the quale as such, but that pattern of its stable relations in experience which is what is implicitly predicated when it is taken as a sign of an objective property" (pp. 124–125). Moreover, it is not about the datum even as standing in certain relations, that objective judgments are possible. "Whatever the uniformity of reality required for knowledge may mean, it *cannot* mean a fixed and uniform sequence in which the given experience is one complete term" (p. 358).

Now if the datum as such is not the subject of my judgment it is not merely true but a truism that it does not in itself determine the truth of that judgment – for the judgment is about something else. I am also not "compelled" in my estimate of Mr. Hoover's administration by the present output of textbooks on anthropology, since the state of the book trade in this particular is not conclusive one way or another on the point at issue. Why should it have seemed important, then, to emphasize this not very recondite point?

Precisely because on the dialectical theory it is assumed that if I am free so far as the datum is concerned I am free altogether. "The rest is purely and simply my problem of interpretation." But quite emphatically it is not. For to classify the datum as an instance of a certain concept is to predict of it that it will stand in discoverable relations to other experiences, such that *if* I follow up my present hypothesis the results anticipated will occur. "Thus the classification of what is presented and the predicted relationship of it with further experience is *one and the same thing*. This implicit prediction is at once a general principle and our concept of the object" (p. 134).

Further, "The ascription of reality is, then, the affirmation of possibility, and the kind of reality ascribed conforms to the nature of the possibility affirmed" (p. 183). If we now recall that it was in classifying the datum as

reality of one or another sort that the mind was said to be "legislative," the following statement is simply crushing as against the "dialectical" view. "The 'if' here [in the if-then propositions which *are* our 'interpretation' of the object] depends upon our own active nature for its meaning, as has been pointed out, but the content of the 'then' clause, and the truth of the proposition as a whole, are things with respect to which the knowing mind is not dictator but dictated to. I may confront the given with different attitudes and purposes; I may proceed into the future in different ways. But *what I should then find*; what eventuation of experience is genuinely possible; that is something independent of any purpose or attitude of mine. These I seek correctly to anticipate in my present interpretation of the given. If they do not obtain in reality, my present "knowledge" is false. Whether they obtain or not, is determined independently of my mind. If not, then it is not determined at all, and knowledge and error are, both of them, purely subjective and meaningless" (p. 193). These relations, these possibilities of experiences, are what our concept of the object is about, and we now see that there is nothing more clearly independent of any attitude or legislative act of our own.

2. The dialecticians will next object, no doubt, that while this holds good of empirical connections, it does not hold for those that are definitive and hence, like any definition, neither true nor false. Now there is a sense in which a declaration about our intentions as to the use of words is neither true nor false, but that is not the meaning of definition that is relevant here. For the dialectician must hold that definition is *at once* only such a declaration of intention *and also* a prescriptive law for physical reality. Mr. Lewis tells us that "*all* definition and *all* concepts exercise this function of prescribing fundamental law to whatever they denote, because everything that has a name is to be identified with certainty only over some stretch of time. The definition provides criteria of the thing defined which, in application, become necessary and essential laws of its behavior" (p. 257). So a definition can "correspond to a natural cleavage" and be "correlated with important uniformities of behavior," which a command addressed merely to ourselves could hardly do. And so, although he has once told us that "the a priori does not dictate to nature" (p. 304), Mr. Lewis later states that "as the matter is usually conceived, this knowledge which we find to be a priori would be included in what is meant by "knowledge of nature," since it delimits, for example, the physical and prescribes basic laws which must be true of all physical reality" (p. 311). And so far is Mr. Lewis from rejecting the "usual conception" that he finds in this *a priori* delimitation of the physical a "basal minimum of law"(p. 322) on which the natural sciences can depend.

If a definition is *merely* a declaration of intention as to what *we* will do, it does not provide certain knowledge of physical objects, since it is, as such, neither true nor false. If it does "provide necessary and essential laws," then

we must accept the responsibility of inquiring whether "natural cleavages" will or will not sustain them. It is only by holding both that a definition "cannot be false" and also that it "creates truth" that the dialectician can maintain his position.

3. There is still the consideration that "the *a priori*" is free with respect to experience, since experience can not refute it, and hence, whatever the "independent reality" may be, it is always possible *in experience* to retain an attitude freely taken. This contention rests, however, on a really shocking ambiguity in the use of the term "experience," and one which Mr. Lewis himself renders peculiarly vulnerable. Of course *bare* experience can not refute any generalization, since it does not as such provide a relevant instance. "*This*" can not disprove the assertion that "all men are mortal" unless "this" is a man. And it is always open to me to hold that "this" is not a man. Nay, more, if "this" means the bare datum as such, I can say most positively that this is *not* a man, since, as Mr. Lewis has shown, the datum as such is *never* the subject of generalizations of this sort. Experience is then not "limited" by my interpretations, since experience is not the subject to which they refer. So far as they are concerned, anything in the way of future experience is possible. "The *a priori* imposes no limitation upon the future possibilities of experience" (p. 231). And again: "They [our interpretative attitudes] dictate nothing as to the content of experience and no experience can conceivably prove them invalid" (p. 266).

But this is not the way Mr. Lewis usually writes of experience. "The possession of the concept or meaning is utterly irrelevant to any experience whatever, unless we could – with sufficient time and attention at least – say whether certain eventualities of experience would or would not be compatible with its application" (p. 286). Now if the *a priori* imposes no limitation on future experience then the whole distinction between what is and what is not compatible with it becomes simply meaningless, and the *a priori*, failing to provide a test of such compatibility, becomes "utterly irrelevant to any experience whatever." Yet Mr. Lewis rightly holds that *a priori* concepts are not thus irrelevant, but rather, like purposes, "must take their shape and have their realization in terms of experience; the content of the given is not irrelevant to them" (p. 24).

In another place he speaks of "the given" as excluding certain interpretations, on the ground, presumably, that the interpretation is incompatible with them. "I can apprehend this thing as pen or rubber or cylinder, but I can not, by taking thought, discover it as paper or soft or cubical" (p. 52). Yet surely, being or not being paper is no part of the brute "quale" as such. Again we read that "The qualia of the given are the clue to the applicability or inapplicability of concepts, and set the limits of conceptual interpretation" (p. 157). How this could be unless experience itself could contradict certain hypotheses, it is difficult to understand.

Hence if we treat of experience *as categorized,* not in its mere qualitative indeterminacy, we must hold of it that it *is* limited by the *a priori.* And Mr. Lewis does hold exactly that. "When we study the sciences of physical reality, we have this *priori* knowledge of principles to which the given must conform if it fall within the class of those phenomena which are significant in this connection. Thus we are provided, a priori, with a basal minimum of law within the field, as a sort of Archimedean point for all investigation" (p. 322).

But suppose the given does *not* fall within the class of such phenomena? This, too, is a matter of discovery, not of mental legislation. Even though we rule it out as unreal, we are still conforming to *its* nature. For "to be able to classify what is presented as 'unreal' or 'illusion', though it may represent only superficial understanding, means nevertheless a very important understanding, precisely because it means that this context of experience is not relevant in the present connection, that it can not figure as a negative instance of an empirical generalization and so on" (p. 350).

Moreover, whatever in experience does not fall within *this* class, does fall within some other, and is hence limited in its own appropriate category. "Nothing is real in all categories; everything is real in some categories" (pp. 321–322). "What is not reality of one sort is reality of another; what we do not understand in one way we shall understand in another" (p. 225). And most emphatically, "every given content of experience is a reality of some sort or other" (p. 11).

We conclude, then, that every experience is limited in the categories under which it falls, that every given experience falls under some categories, and that whether or not it falls under a particular one is a question of objective relevance or irrelevance. Its nature in each case is perfectly determinate, and in no case is the mind free to legislate for it in its appropriate categories, or to discover it as other than it independently and determinately is.

Finally, the fact that there should be such limitation of experience is something absolutely inescapable, and something itself not made by mind. For there is no possible alternative. If experience were not limited in *some* fashion it would be simply inconceivable. "Since what any substantive concept denotes in experience is some definite sequence or set of such, there could be, in an experience that was subject to no limitation upon the all-possible sequence of given presentations, no recognition of things by their appearances as even probable" (pp. 370–371).

It is true that Mr. Lewis describes this requirement that experience should be limited in its possibilities as not itself a "limitation on experience" in precisely the opposite sense to that in which he formerly used the term. It is no doubt true that in eliminating from the world the impossible we are not eliminating anything possible. But the decision as to what is possible and what is not is here most rigidly fixed. On the other hand, "The a priori is a peculiar possession of mind because it bears the stamp of mind's creation. And the

criterion of creativity is not inevitability but precisely its opposite, the absence of impulsion and the presence of at least conceivable alternatives" (p. 213). Hence in the necessary limitation of the possibilities of experience we are dealing preëminently with that which is *not* the creative work of the mind, because there are no conceivable alternatives. I do not for a moment contend that Mr. Lewis actually means to hold that the denial of limitation with which he has ended – the absence of conceivable alternatives – is identical with the denial of limitation with which he began – the presence of conceivable alternatives. But I do hold that only when the two are identified – when we equate what the mind can not help thinking about an ordered world with what it "freely" elects to take as its own classification of the data of experience – does the dialectical theory of truth become even apparently plausible. And it is for that reason, among others, that the theory seems to me untenable.

I conclude therefore that no statements that truly prescribe laws to physical reality are made true by the decision as to how we shall classify the data of experience. The only statements in fact that are made true by our decision to mean one thing rather than another are those which assert that such in fact is what we have decided to mean by them. In all its knowledge – *a priori* or other – the mind intends to follow the nature of its subject-matter, not to legislate for it. "I am coerced only by my need to understand." True enough, but that is the most rigorous coercion of all. "For the purpose of knowledge is to be true to something that is beyond it. Its interest is to be governed and dictated to in certain respects. It is a real act with a real purpose because it seeks something which it knows it may miss. If knowledge had no condition independent of the knowing act, would this be so?" (pp. 191–192). And clearly it is not just the datum that here "dictates" to knowledge, for the datum, as infallibly given, is not something that we may miss and, moreover, our awareness of it is, for Mr. Lewis, not knowledge at all. It is the object of our interpretation that "governs" here, and if the mind is "free" with respect to it, it must be because, in Rousseauistic terms, it is forced to be free. The most thorough-going realism could not ask for a more decisive statement.

Yet it is not wholly satisfactory simply to oppose one theory by its contradictory in this somewhat abrupt fashion. A really adequate criticism must account for the mistake in question – if such it be – and exhibit it as a partial, though quite inadequate, expression of the truth. For, as Spinoza said, "just as light shows itself and darkness also, so truth is a standard of itself and falsity" *(Ethics*, Bk. II, prop. XLIII, note). It is the outstanding merit of this second view, which Mr. Lewis so emphatically holds, that it can give such an account of the dialectical theory from which its own results diverge so sharply. An exposition of this point will constitute our final evidence in its favor.

The plausibility of the dialectical theory rests throughout on a mistake about the relativity of knowledge which Mr. Lewis exposes with admirable clarity.

It is perfectly true, as has been seen, that where a term – such as "reality" for example – is systematically ambiguous, a specification of meaning is required before statements that concern "the real" can become determinately true or false. This is true, of course, not because the term refers to no object, but because it may refer to any one of many and the selection of the one in question is essential for unequivocal reference. The determination of such reference does not make a proposition true; it is its object that does that. But it does indicate that object and hence bring us to the position where the proposition may be *either* true *or* false. To confuse this resolution of ambiguity with the creation of truth is a subtle and fashionable mistake, but one that needs special criticism for that very reason.

Thus when the skeptics of our own day observe sapiently of the truth of any proposition that "it all depends on what you mean" the appropriate retort is simply "Well, what *do* you mean?" Apart from specification of this sort the truth of the proposition can not be determined because it is as yet no definite proposition at all. To linger among these deliciously indeterminate half-lights of possible interpretation, to transform the need of reaching a decision about meanings into an apology for never doing so – this is dialectic in its most modern dress, the last resource in philosophy of that variety of literary loose talk to which some of the disciples of Santayana seem so fatally addicted.

But once meaning *is* specified the determinate truth or falsity of the proposition depends on what? – why, on the nature of its object, of course. The determination of meaning can only bring the proposition to the status of being *either* true *or* false – it can not decide between these alternatives. So exactly Mr. Lewis has made the point in the case of another instance of relativity – that of motion. One must specify which among possible reference systems one has in mind before one's assertion about the motion of an object can have a definite meaning. "That is, there are certain properties of the object, as an independent reality, which can only be described in terms of some observer or frame of motion. But specify this relationship and the true description is thereby fixed. What is it that determines this? It can not be the relative motion already specified. It is fixed by the objective real character of the thing" (p.185).

So of experience. It has many possible connections, hence many meanings. No one of these – as opposed to any other – is exclusively prescribed for our attention by the nature of the "datum as such." To select those relations which we mean to emphasize is a work for mind, and a vital one. In this sense, as Mr. Lewis observes, "A large part of the scientific search is, thus, for *things worth naming*" (p. 258). But once this selection is made, the truth depends on what we are talking about, on the object to which a proposition actually refers. It is the independent nature of the object, *thus specified*, that "creates truth" about it.

And thus to imagine that because we must know what we are talking about we are thereby absolved from the necessity of conforming to its nature, is a sheer *non sequitur*. It is parodied by Mr. Lewis in another connection in the following terms: "The size of Caesar's toga is relative to the yardstick or to some other standard of measure. No size without a yardstick. The size of things is through and through yardstickian. To be sure the fallible yardstick in my hand may not determine size in general, but the yardstick in the Bureau of Standards determines both my yardstick and all sizes that there are. It creates size" (p. 189). If the reader will compare this statement with one previously considered: "Mind makes classifications and determines meanings; in so doing it creates that truth without which there could be no truth" (p. 240), he will see that this latter assertion simply can not support the interpretation which a "dialectical" theory would put upon it.

It was Bacon, I think, who said that a little philosophy turns men from religion: but a deeper philosophy brings them back to it. So we might say of "relativism" in the theory of knowledge, that a little of it appears to discredit realism, but a more accurate account of it justifies an objectivity for knowledge more precise and more thoroughgoing than could previously have been claimed. Mr. Lewis's view of the relativity of knowledge is our best evidence that this second stage in the development has actually been achieved.

LOGICAL POSITIVISM AND PROFESSOR LEWIS

James B. Pratt. "Logical Positivism and Professor Lewis." *Journal of Philosophy* 31.26 (20 December 1934): 701–710.

In their work on *The Meaning of Meaning* Ogden and Richards cite some eighteen definitions of the word, most of which are obviously unsatisfactory, adding one of their own which many of their readers consider no better than it should be. Miss Calkins, in one of her last articles,[1] distinguishes seven uses of "meaning," and comes to the conclusion that the word is so ambiguous that it had better be systematically avoided. One can understand the reasons for this advice. Yet if philosophers should follow it they would find themselves falling back upon some synonym or partial synonym; for the meaning of "meaning" is so crucial that it can not be avoided. The purpose of this paper is not to add a new definition to this slippery and unreplaceable word, but merely to point out one aspect of meaning which the work of the logical positivists has brought to the fore, and which has bearings of some importance upon certain questions not only of logic but of metaphysics.

For, as all readers of this paper will know, the logical positivists are convinced that many of the traditional problems of metaphysics can be solved in the sense of being shelved by the *Konstitutionssystem*; and the method by which this solution is brought about consists in showing that the problems in question are, in the last analysis, without meaning. There are two kinds of assertions, we are told, in the official declaration of the Vienna Circle; to one of these belong strictly scientific views and conclusions; the other kind, such as most metaphysical positions, prove to be entirely meaningless. "The metaphysicians and theologians, failing to understand themselves, believe that they are saying something with their assertions. Analysis shows, however, that these assertions say nothing at all but are merely expressions of life-feelings."[2]

I can not find in the writings of the logical positivists a statement of the nature of meaning which seems to be intended as a complete summary of their doctrine, but we shall hardly be far wrong if we put together the essence of

[1] In the *Am. Jour. of Psychol.*, Vol. XXXIX, pp. 7–22.

[2] *Wissenschaftliche Weltauffassung der Wiener Kreis*, p. 16.

their treatment of this question, especially as found in Carnap's *Logische Aufbau der Welt*, in some such way as this: The touchstone for testing the meaning of any proposition is to be found in the question, Is the proposition verifiable in terms and relations of the most elementary sort (after the most complete analysis) within the private experience of the individual? I have here put into one sentence three separate (though related) tests of meaning, each of which receives great emphasis by Carnap and his followers. Having put them together for the moment let us now consider them separately. A proposition to have meaning (1) must be reducible to the most elementary terms that analysis can find, (2) must be reducible to the elementary terms of first-person experience, (3) and must be verifiable in these terms.

The first of these three tests is obviously fundamental to the whole conception of the *Konstitutionssystem*. As applied by Carnap it usually seems to identify the ultimate and unanalyzable psychic atoms with sense qualities. Whether this identification is intended as complete or not, at any rate it is plain that the theory stands by the view which identifies an object or experience with its parts. Against the common idealistic belief (which is Aristotelian as well as Platonic) that parts get their character from wholes, the position of the logical positivists interprets wholes entirely by the parts into which analysis transforms them. In this respect logical positivism would seem to be closely related to structural psychology and to have a good deal in common with old-fashioned associationism. Analysis has succeeded in reducing the consciousness of meaning in the subject-object relation and the experience of activity to sensational elements; but one wonders whether in so doing it has not poured out the baby with the bath. It is not my purpose here to argue this matter, but merely to point out that the denial of meaning to all assertions concerning the less sensuous experiences of the human mind until they can be reduced to and replaced by assertions concerning simple psychical elements is something which requires larger discussion than it receives in the *Logische Aufbau der Welt*. Some readers may feel that there is something almost naïve in Carnap's dogmatic confidence in analysis.

It is the second and third tests of meaning in which I am particularly interested. For Carnap the primacy in knowledge and meaning of what he calls the *eigenpsychische*, the conscious content of the individual, is fundamental. From it the meaning of physical objects is derived, and only through physical objects (the bodies of other persons) is the meaning and knowledge of other people's psychic states – the *fremd psychische* – derivable.[3] *The Konstitutionssystem* has thus what Carnap calls a "*solipsistische Basis*." There is excellent justification for this as a starting point for any attempt to put meaning into science and philosophy. No assertion can have meaning for

[3] *Der Logische Aufbau*, section 58.

anyone the terms of which are not interpretable by him in terms of his own experience. In the application, however, of this admirable pragmatic principle there are certain difficulties, notably the question how with this principle one can avoid subjectivity. Science, as the Vienna school insist, is a *Kollektivarbeit*,[4] and demands objectivity. The reality which it studies, in contrast to dreams and illusions, must possess "*Intersubjektivität*" and "*Gültigkeit für die anderen Subjekte.*"[5] All this is not only admitted but stressed by Carnap. The solution which he gives to the problem reads thus: "The material of the individual streams of consciousness is indeed entirely different, but certain structural characteristics are common to all. Science must restrict itself to assertions concerning these structural characters if it is to be objective."[6]

That science must deal with structure and relations rather than with the purely subjective in its intimate privacy is an important and helpful insight. But that this insight can get us out of the subjectivity with which we start – our "*solipsistische Basis*" – it is impossible for me to see. Before one can put meaning into the assertion that different streams of consciousness can have identical structures, one must have put meaning into the conception of different streams of consciousness. The central problem of the meaning of the *fremd psychische* is thus, so far, untouched. Nor are we in any wise aided in its solution by the fact, upon which much stress is laid, that one reason for believing in the existence of other psychic streams than our own is to be found in our perception of other people's physical bodies and their behavior. This is true; but before we are to believe in other conscious centers than our own we must know what we mean by them. The most fundamental part of the solution to this problem of deriving the objective from the subjective Carnap gives rather casually in a section of his work which does not purport to deal primarily with this problem: "We *ascribe* to the human bodies which we see psychic processes"; and these psychic processes, thus ascribed, are conceived as *eigenpsychische*.

In other words, Carnap would seem to hold (and in this I should heartily agree with him) that the only way in which the concept of other minds or of an objective world can be given meaning is through the use of the imagination. Here let me explain that I am using the word "imagination" in a sense wide enough to include conception in both its universal and its individual sense. Taken in this inclusive fashion, I hold that the function of imagination in the production of meaning is of primary and crucial importance. The avoidance of metaphysical solipsism, the recognition of society, the *Objektivität*,

[4] *Wissenschaftliche Weltauffassung*, p. 15.

[5] *Logische Aufbau*, Section 66.

[6] *Loc. cit.*

Gültigkeit, *Intersubjektivität* of the physical world, the reality of science as a *Kollektivarbeit*, all are dependent for meaning upon our power of extending our own experiences through the imagination, and attributing some of the qualities which form parts of the content of our awareness to other existences – whether psychical or physical – than our own streams of consciousness. The term "*other streams of experience*" is meaningful to me only because I have experienced my own experience and, within this, have experienced what I know as otherness, and through these experiences am able to imagine or conceive another experience which is not mine. I am thus able to conceive what I do not directly experience. Unless I could do that, not only all knowledge, but all meaning, would be unthinkable.

It is quite likely that Carnap would assent to what I have said. But it would be possible to interpret some of his passages in the sense that all physical objects and all other minds, if they are to have meaning for me, must be envisaged as parts of my own first-person private experience, my *eigenpsychische*. It is no part of my purpose, however, to give a complete exposition of Carnap's view; I shall therefore leave the matter with the repeated insistence that (private) experience plus imagination is amply able to put meaning into assertions concerning things outside of our psychic content; and that without imagination all thought *about* anything would be impossible.

The third test of meaning which Carnap seems to insist upon (I confess I am not fully certain how his words should be interpreted) is the possibility of verification. Nowhere, so far as I recall, do any of the logical positivists specifically state that the unverifiable is meaningless, but it is implied in many of the positions which they adopt. This, in fact, would seem to be the chief reason why metaphysical positions of various sorts are considered meaningless. It may be that in attributing this position to Carnap I am doing him injustice; but whether he would make verifiability a criterion of the meaningful, the identification is worth consideration on its own merits. And certainly there are passages in Carnap's book which look in this direction. A specific example of the kind of statement I have in mind is Carnap's definite assertion, "*es gibt kein Fremdpsychisches ohne Leib*," – there is no psychical existent outside of my own consciousness without body.[7] The reason for this assertion is stated as follows: "*Fremdpsychisches* can be constructed (*konstituiert*) only through the means of a body in which expressive processes take place which are like those of my body; or, in realistic terms, *Fremdpsychisches* which was not bound to a body through which it got itself expressed would be fundamentally unknowable (*unerkennbar*), and therefore could not become the object of scientific assertions."[8] There is no doubt that this

[7] *Op. cit.*, Section 140.

[8] *Loc. cit.*

proposition is in part true; but the truth in it is the fact that the normal and usual mode of verifying a belief in the *Fremdpsychische* is through the appearance and activity of a living body. This, however, is not what Carnap means. The whole method used by logical positivism for the exclusion of various "metaphysical" assertions consists, not in an appeal to empirical evidence, but in an attempt to show that the assertion under criticism is finally meaningless. The argument here used to show that there can be no *Fremdpsychische* without body is, therefore, an attempt to show that there could be no meaning in the conception of a discarnate consciousness. Such a form of consciousness, it is said, can not be because it would be "fundamentally unknowable." *Knowable* or *verifiable* is thus used as synonymous with *meaningful.*

It would require, I think, no great amount of argument to show that such a use of meaningful would make nonsense of most of our intellectual processes. Verifiability surely presupposes that there is some concept with a meaning to be verified. When you assert, "I am not sure whether a given assertion is true," you must know what the assertion means or you are not saying anything at all. It would not be difficult, moreover, to suggest a number of cases in which we discuss with each other unverified and even unverifiable propositions. Take the very example involved in the sentences quoted from Carnap – the existence of discarnate streams of consciousness. Many students of "psychical research" assure us that such disembodied minds exist. The evidence, they tell us, indicates the reality of such minds as the most probable cause of responses and events otherwise incapable of explanation. You, let us say, are not persuaded, and insist that the evidence is not sufficient to justify the conclusion that there are discarnate minds. But you can say this only because you know what you mean by discarnate minds. We may admit that such minds could not become scientific objects, because not socially verifiable; but to say that is very different indeed from saying that the hypothesis of their existence is meaningless.

For the reasons expressed, therefore, it seems rather plain to me that a metaphysical proposition can not be ruled out as meaningless because it can not be verified within my private experience, nor because it can not be verified by any human experience. Meaning is not identical with verification nor with knowledge: it is presupposed by both. It is not a matter of direct experience but of imagination. By its very nature it involves transcendence of the immediately given. It is an awareness that the immediately given psychic content intends to point beyond itself, to be symbolic of something not itself. All the characters attributed in meaning to this intended and imagined object must, indeed, be drawn ultimately from one's own experience; but with these characters there must go an explicit sense of *otherness.* When imagination of an *other* takes place, there is meaning; without it there is no approximation to anything meaningful.

If the interpretation of meaning which I have been defending be true it is impossible to assert with Carnap that realism and subjective idealism really mean the same thing and do not differ in anything that is significant.[9] Surely the question is not meaningless whether the entire physical universe came into being and all the physical processes began only with the first psychical processes. Nor is there any doubt of the meaning of the assertion that the entire physical world will cease to be when it is no more perceived. Neither the realistic nor the idealistic hypothesis may be verifiable, but we know what we mean by each.

It was with considerable satisfaction that last December in the presidential address at the annual meeting of the Eastern Division of the American Philosophical Association I heard views very similar to those I have here expressed, expounded so much better than I can expound them. I am not sure that Professor Lewis would go the entire distance with me, but he certainly goes a long way. For him as for me imagination is essential to meaning, and ample to produce it.[10] For him as for me transcendence of the immediately given is essential to both knowledge and meaning.[11] For him as for me knowledge and meaning are not identical.[12] To be sure, Professor Lewis seems at times to differ, in words at least, from the doctrine I have presented, in that he asserts that verifiability is a necessary criterion of meaning. Such a position, if intended in its more obvious sense, I could not possibly accept. But as Professor Lewis truthfully says, "just what we can mean by 'empirically verifiable' is really a bit obscure"; and by the time he has finished with the adjective "verifiable "there is not enough left in it to divide him from me. The word, he tells us, is capable of two uses. In one it "connotes the possibility of actually satisfying the conditions of verification." In this sense, we are told, verifiability is essential to knowledge but not to meaning.[13] The other use of the word, which is the one adopted by Professor Lewis, requires no such actual and practical possibility of verification. All that is requisite in the hypothesis which is to have in meaning and therefore be "verifiable" is that it should have an empirical content, that it should "be expressed in terms which genuinely possess denotation."[14] Verifiability in any other sense than this is not necessary for meaning. An hypothesis about the mountains on the other side of the moon which we shall never see, an hypothesis

[9] This seems to be the meaning of Section 176.

about immortality which "could hardly be verified by science," an hypothesis about the continued existence of the stars after the death of all conscious beings and when all possibility of verification has therefore ceased – these and guesses like these are all "verifiable" in Professor Lewis's sense. "It is entirely meaningful, for example, to think of those inventions which nobody has ever thought of, or those numbers which no one will ever count; we can even frame the concept of those concepts which no one will ever frame. Those who would deny this on logical grounds exhibit a sense for paradox of language which is stronger than their sense of fact. Furthermore, *imagination is sufficient for empirical meaning*, though it requires *perception* for verification. I can imagine that future time which I shall never perceive; and humans can meaningfully think of that future when humanity may have run its cosmic course and all consciousness will have disappeared. It may be that the hypothesis of a reality with no sentience to be affected by it is not a particularly significant issue; though the idealist might have an interest in it for the sake of the light which decision about it would throw upon the nature which reality has now. In any case, the fact that it is unverifiable has no bearing upon its meaningfulness. Whether this hypothesis is true, is a genuine question about the nature of reality."

"When verifiability" is taken in this rather Pickwickian sense I have no quarrel with it as a criterion of meaning; and it would seem that except for words there is no difference between Professor Lewis's doctrine of the meaningful and that maintained by critical realism. Certainly there is nothing in the treatment of meaning to be found in the presidential address which would make the realistic doctrine meaningless. For the realistic schools of today do not assert the reality of a characterless *Ding-an-sich*. Physical reality, they assert, has characters, and we know what we mean by characters because we find characters within our experience. It has spatial and temporal characters, and we know from our own experience what we mean by spatial and temporal characters. It is other than psychical existents and we know what we mean by *other*. Is it meaningless to imagine a space which is not my spatial experience? Is it meaningless to suppose that certain portions of this space are characterized by qualities? It seems to me perfectly possible to imagine this; and if it is so possible, the hypothesis that reality is as imagined is not meaningless. As Professor Lewis himself points out, when we make the realistic hypothesis that there is another side of the moon we need not specify nor image to ourselves what in detail it is like. But we do suppose that it has characters; that it is determinate. "To speak more precisely, our belief includes alternatives which are not determined; but if the thing believed in is what it is believed to be, these alternatives must be determined in the object."[16]

[15] P. 144 [this volume, pp. ??].

[16] Pp. 137–138 [this volume, pp. ??].

Professor Lewis's doctrine of meaning is therefore in no wise inconsistent with representational realism; and he can not consistently reject realism on the ground that it, or its assertions, are any whit less meaningful than are those of his own doctrine. His real objection to realism is based not on the question of meaning, but on the question of knowledge. The difficulty that he finds with realism lies in the realistic view that the object of knowledge may transcend experience in general – i.e., not be itself existentially a part of any stream of consciousness. Transcendence of this sort is, in his opinion, irreconcilable with the possibility of knowing the object.[17] "A relation of experience to what can not be brought within experience is a relation which can not be investigated, and one the very conception of which as cognitive involves a confusion of thought."[18]

Considerable light would have been thrown upon Professor Lewis's criticism if he had told us more explicitly in what this "confusion of thought" lies. The "confusion" can hardly be due to lack of meaning in the realist position, for we have seen that upon Professor Lewis's doctrine realism is quite free from that charge. The alleged confusion is probably to be found in the realist's assertion that objects which are not existentially parts of experience – are not made of experience stuff – can still be known. If this is the case it would seem that the "confusion" is in large part that of Professor Lewis. When the question is raised, How is knowledge possible on the realist's view? it is necessary first of all to consider the meaning of "knowledge." And as everyone knows, the word has the two senses of (1) direct experience, or "acquaintance with," and (2) conceptual knowledge, or "knowledge about." Now if the realist should say that an object which is not existentially within the stream of experience can be directly experienced, can be an object of "acquaintance with," he would obviously be guilty of a confusion of thought, not to say a self-contradiction. But when the realist speaks of our knowledge of external things he is using the word in the sense of conceptual knowledge or knowledge about. No realist claims that we are acquainted with material reality from within.[19] It is not inner nature but relations and structure that are the objects of our knowledge in the physical world.

This being the kind of knowledge which realism claims that we possess, it is hard to see how any confusion of thought is involved. The realistic hypothesis as to the physical has a perfectly definite meaning. How does it differ in principle from our knowledge of other people's experience? Possibly Professor Lewis's objection to calling it knowledge may be explained by a

[17] P. 132 [this volume, pp. ??].

[18] P. 135 [this volume, pp. ??].

[19] A few realists (e.g., Professor Sellars) suggest that we know our own brains in this inward fashion – but not as brains.

sentence on page 142 of his address: "Knowledge requires the *assurance of truth*; and whatever would prevent actual verification may prevent such assurance." It is true that knowledge requires a certain amount of verification while meaning is entirely independent of it. But outside of mathematics and logic, where have we complete verification? If absolute assurance is requisite to knowledge, can we really be said to know or to know about other people's experiences? Do we have knowledge in this sense even of our own remembered past? The truth seems to be that in all cases of empirical knowledge, the best that we have is well-grounded hypothesis. When we are dealing with the world of existence, our knowledge is not certain but at best probable.

The important question about the realistic position is not, then, Does it possess meaning ? – for no one (and surely Professor Lewis least of all) can successfully deny that it is meaningful. Nor is it the question, Does the realistic hypothesis carry with it absolute assurance and certainty? – for no hypothesis about the existent and empirical is more than probable. The relevant and important questions read thus: (1) Is the realistic hypothesis well grounded? and (2) If it be well grounded, can our assertions about physical objects and events be sufficiently probable to deserve the name "knowledge"? The answer to the second of these queries will, of course, vary according to the particular assertion and the amount of evidence to be found in its favor. As to the first question, it would seem that the hypothesis of an existent physical realm which has a structure of its own, independent of what we think of it, and which is causally related to our experiences, is justified by the same general principle as that which justifies us in rejecting solipsism and accepting, instead, the hypothesis of other minds. For how otherwise are we to explain not only the fact that we get experiences which we do not make and which we did not anticipate, but the more challenging fact that a plurality of people get similar experiences at the same time, that the experiences of the entire human race, in all their qualities and in all their spatial and temporal details, occur, and always have occurred, exactly *as if* there were a physical world acting causally upon us all?

The fact of this interrelation of our experiences is undeniable. The coincidental nature of the experiences is so extraordinary as to cry out for an explanation. The realistic explanation is simple, meaningful, and obvious. What is Professor Lewis's explanation? He rejects the realistic answer; what does he give us in its place? So far as I can discover he gives us nothing. He has no explanation. He leaves us in an inexplicable welter of chance coincidences that have characterized the experience of the race since the dawn of consciousness, and suggests not even the hint of an hypothesis which will throw any light upon this extraordinary situation.

If one compare Professor Lewis's position with that of the logical positivists, and likewise if one compare the book, *Mind and the World Order*, with the presidential address, one can see notable advances. Professor Lewis sees

clearly that meaning is dependent not on verification but on imagination, and he seems to understand that the realistic doctrine fulfills all the requirements of meaning. As yet, however, he has avoided the significant question how the extraordinary coördination of our human experiences is possible. If he will ponder seriously over this question and seek to give us a definite answer to it, I have little doubt that his next position will be one step nearer still to some form of representative realism.
